Dental Health Needs Assessment for Merseyside

Louise Roper, Janet Ubido, Chris Williamson, Rebecca Harris, Paul Wright, Alex Scott Samuel

LPHO Report series number 105, March 2015
Acknowledgements

Special thanks to:

Chris Williamson and Sharon McAteer for their guidance and contribution to the drafts;

Paul Wright (Specialist Public Health Information Analyst, Cheshire West and Chester Council) for producing the maps;

Rebecca Harris (Honorary Consultant Dental Public Health, University of Liverpool) for the 'dental access' literature section;

Public Health England Dental Consultants Yvonne Dailey, Lesley Gough & Keith Milsom for their on-going support;

Rob Wise (Information Analyst, NHSBSA Information Services) for dental activity data.

Thanks also to the other steering group members, to everyone who was involved in providing data and to those who responded to the telephone survey.

Steering group:

Yvonne Dailey, Consultant in Dental Public Health, Public Health England

Dympna Edwards, Assistant Director of Public Health, St. Helens MBC

Lesley Gough, Consultant in Dental Public Health, Public Health England

Emma Higgins, Public Health Intelligence Team Leader, Sefton MBC

Sara Kinsella, Public Health Information Specialist, Wirral BC

Paul Langton, Public Health Epidemiologist, Knowsley MBC

Sharon McAteer, Public Health Development Manager, Halton BC

Keith Milsom, Consultant in Dental Public Health, Public Health England

Jill Oakley, Public Health Intelligence Manager, Cheshire West and Chester Council

Louise Roper, Research Associate, Liverpool Public Health Observatory

Alex Scott-Samuel, Director, Liverpool Public Health Observatory

Chris Williamson, Lead Public Health Epidemiologist, Liverpool City Council

Terms and Definitions

Dental Health: Dental health refers to all aspects of the health and functioning of the mouth especially the teeth and gums. Apart from working properly to enable us to eat and speak, teeth and gums should be free from infection, which can cause dental caries, inflammation of gums, tooth loss and bad breath. Poor dental health is also linked to chronic illnesses such as heart disease.

FP17: Providers (usually dental practices) submit forms to the NHS detailing dental activity data. The data recorded on the FP17 form shows the patient charge collected, the number of units of activity performed and treatment banding information.

Health Needs Assessment (HNA): a systematic method for reviewing the health issues facing a population, leading to agreed priorities and resource allocation that will improve health and reduce inequalities.

Liverpool City Region (LCR): In January 2009 an agreement was made that the local authorities of Halton, Knowsley, Liverpool, Sefton, St Helens and Wirral would form LCR in a multi area agreement.

Liverpool Public Health Observatory (LPHO): LPHO was founded in 1990 and provides public health research and intelligence for the Liverpool City Region local authorities. LPHO is situated within the University of Liverpool’s Department of Public Health and Policy.

Public Health England (PHE): was established on April 1st 2013 to bring together public health specialists from more than 70 organisations, including the former Health Protection Agency (HPA), into a single public health service. PHE works with national and local government, industry and the NHS, to protect and improve the nation's health and support healthier choices. PHE is addressing inequalities by focusing on removing barriers to good health.

Oral Health: Oral health is a state of being free from chronic mouth and facial pain, oral and throat cancer, oral sores, birth defects such as cleft lip and palate, periodontal (gum) disease, tooth decay and tooth loss and other diseases and disorders that affect the oral cavity. Risk factors for oral diseases include unhealthy diet, tobacco use, harmful alcohol use and poor oral hygiene (WHO definition)\(^1\).

Units of Dental Activity: Dentists or dental practitioners providing their services to the NHS in England and Wales are paid according to how many "Units of Dental Activity" (UDA) they do in a year. The average value is around £20 per unit of dental activity and it varies around the country.

\(^1\) [http://www.who.int/topics/oral_health/en/]
Usually the more need of dentists and NHS dental provision there is in an area, the more a UDA is worth. For band 1 treatment (the most routine) the dentist is paid 1 UDA, for band 2 treatment, 3 UDAs and for band 3 treatment 12 UDAs. UDAs are awarded for completed treatments; therefore if a dentist provides a treatment with crowns, they will report 12 UDAs as this is the accepted rate for this treatment. It does not matter if it is 1 crown or 10 crowns, 12 UDA’s are still reported.

**Individual local authority summary reports**

The individual local authority summary reports are presented on the following pages i to xx,

- Halton p.i - iv
- Knowsley p.v - viii
- Liverpool p.ix - xii
- Sefton p.xiii - xvi
- St. Helens p.xvii - xx

The summaries are followed by the full main report which starts on p.1.
Dental Health Need Assessment
Halton Summary

Aims
The aims of this dental health need assessment were to determine the current health needs of the population, to investigate the current service provision for dental health in children and adults, highlighting gaps and inequalities. We also developed a set of evidence based recommendations for local commissioners on oral health promotion and prevention and for NHS England on the provision of dental health services for the local population; from Cheshire and Merseyside, through to local authority level.

Key recommendations for improving dental health in Cheshire and Merseyside

Increased provision of data
- Utilise public health and ward level data (where available) to help inform commissioning intentions and decisions.
- Explore the needs of people on low incomes but who are not exempt from dental charges.
- Undertake an additional health needs assessment into domiciliary dental care provision.

Targeted interventions
- Place oral health needs on a wider agenda for change in order for collaboration with relevant sectors and agencies to take place, for example linking with related public health programmes such as healthy eating.
- Work towards a multi-partnership oral health programme strategy for older people.
- Pursue fluoridation of public water supplies.

Improved knowledge of oral health, sharing of good practice and reporting of information
- Encourage local authorities to share good oral health practice and procedures.
- Explore tobacco cessation and alcohol awareness training for dental practices.
- Monitor NHS access to dental care at regular intervals.

Evidence of oral health promotion in Halton
The Oral Health Promotion service provides support for early years settings and schools, and special schools. It is responsible for the implementation of a Supervised Tooth brushing Programme (STB) with Early Years establishments (including Children’s Centres), primary and special schools. There are currently 32/50 establishments participating, with 1,926/2,135 consented to brush. It supports training for teaching staff and children, and delivers the ‘Tasty Tuck 4 life’ with the Health Improvement Team.
in Halton, and provides a Resource Box Loan scheme, as well as support for PSHE (personal, social and health education) meetings with the Health Improvement Team.

The team also support children's centre staff and parents with the “Terrific Twos” sessions. They provide on-going training and support for health visitors. They also provide staff training in care homes, linking with Healthwatch Halton.

Oral health promotion in relation to learning disability in Halton is as follows:

- 5 Borough’s Partnership via the Bridges Team provide advice in their skills for life groups for people with learning disability on their 6 week programme
- Community Matron and speech therapist provide advice on oral hygiene and mouth care during initial and repeat visits
- Dental accessible information and social stories are used to encourage access to dental departments using photographs and accessible person-centred information for the client
- Discussion over oral health and access to dental care is part of Learning Disabilities Directly Enhanced Service yearly health check provided by GP practices or Learning Disabilities Community Matron
- Referral forms are in place re proactive referrals for check-ups for use by all Learning Disabilities staff
- Home visits are provided via community services to anxious clients who are unable to attend dental clinic bases.

**Dental Health in Halton**

Evidence suggests that the health of people in Halton (population 126,000) is generally worse compared with the average health of the population in England. Deprivation levels are higher than the national average. The Health Profile for Halton can be found by following this link: [http://www.apho.org.uk/default.aspx?QN=HP_FINDSEARCH2012](http://www.apho.org.uk/default.aspx?QN=HP_FINDSEARCH2012) with some more recent data available here: [http://fingertips.phe.org.uk/profile/health-profiles/](http://fingertips.phe.org.uk/profile/health-profiles/)

The common risk factors to poor oral and dental health include unhealthy diet, smoking and harmful alcohol use. Available indicators would suggest that Halton compares worse than the national average for most of these risk factors. The dental health of local populations is difficult to determine as only limited data is collected, usually related to the health of children's teeth. In Halton, around 1 in 3 (33.6%) children aged 5 have decayed, missing or filled teeth. This is higher than the England average of 27.9%, but lower than the North West average of 34.8%. See main report for further findings.

**Dental Access in Halton**

Child dental access rates in Halton are better than the England average for all ages (Figure A). Adult access rates are 58.1%, which is higher than the England average of 52.0%. Research has shown that dental disease correlates closely with social and economic deprivation, meaning that usually, dental
need is greater in areas of deprivation and in areas of prosperity, dental need is less\(^2\). There has been a reported seven fold difference between the populations of (former) PCTs in England with the best dental health compared to those with the worst dental health\(^4\).

**Practice locations**

The distance travelled to a dentist can be seen as an indicator of need and effectiveness of dental commissioning. In Map A, the red areas are the most deprived nationally, dark green the least deprived. The map shows the geographical location of NHS and private dental practices mapped over the Indices of Multiple Deprivation Quintiles and how in general, the more deprived an area, the more...
dental practices it has. There are still areas of relative deprivation that do not have as much provision of dental practices as might be needed, however, dental practices are more concentrated in areas of deprivation. Map A also plots the location of care homes in Halton. The dental health of vulnerable people, particularly of older people in care homes and the location of practices to care homes is an important consideration for commissioners of services.

The majority of the Halton area has dental practices which are accessible by driving 8.4 minutes by car. However, it is reasonable to expect that not everyone has a car. Not all of the population of Halton can reasonably be expected to walk to their nearest NHS dental practice, as shown in Map B, either walking a 15 minute (orange area) or 30 minute (yellow area) distance.

**Dental Practice Opening Times**

The opening times of practices have an impact on how often the general population can use available dental services. Dental practices are not required to open between specific times although in most areas there are some dental practices which open outside the usual working hours of Monday- Friday 9am-6pm.

Source: LPHO telephone survey, Feb/March 2015

**Patient Satisfaction Information**

The GP Patient Survey Data (2014) reports that the proportion of people in Merseyside successfully able to get an NHS dental appointment is 94% compared to 93% England average, and 53% of Merseyside report experiencing a very good overall experience compared to 48% across England.
Aims

The aims of this dental health need assessment were to determine the current health needs of the population, to investigate the current service provision for dental health in children and adults, highlighting gaps and inequalities. We also developed a set of evidence based recommendations for local commissioners on oral health promotion and prevention and for NHS England on the provision of dental health services for the local population; from Cheshire and Merseyside, through to local authority level.

Key recommendations for improving dental health in Cheshire and Merseyside

Increased provision of data

• Utilise public health and ward level data (where available) to help inform commissioning intentions and decisions.
• Explore the needs of people on low incomes but who are not exempt from dental charges.
• Undertake an additional health needs assessment into domiciliary dental care provision.

Targeted interventions

• Place oral health needs on a wider agenda for change in order for collaboration with relevant sectors and agencies to take place, for example linking with related public health programmes such as healthy eating.
• Work towards a multi-partnership oral health programme strategy for older people.
• Pursue fluoridation of public water supplies.

Improved knowledge of oral health, sharing of good practice and reporting of information

• Encourage local authorities to share good oral health practice and procedures.
• Explore tobacco cessation and alcohol awareness training for dental practices.
• Monitor NHS access to dental care at regular intervals.

Evidence of oral health promotion in Knowsley

Following the oral health promotion review in 2014, many existing programmes to prevent dental caries in children were expanded. Knowsley local authority has commissioned a range of oral health
programmes aimed at improving oral health – particularly child dental health which is a local priority. A prioritisation exercise was undertaken in 2014 to inform the re-commissioning of these programmes. The Public Health England (PHE) guidance document for local authorities, ‘Commissioning Better Oral Health’, was used as a reference document for the prioritisation exercise. A prioritisation tool developed by the NHS Institute for Innovation and Improvement was used for the exercise.

Based on the prioritisation exercise it was agreed that a postal fluoride toothpaste programme targeting 3-12 year old children and toothpaste distribution programme via health visitors were the top priority programmes. The postal toothpaste programmes target just under 20,000 young children in Knowsley – children receive a toothbrush and fluoride toothpaste pack together with an information leaflet twice a year through the post.

Through the prioritisation exercise a number of other programmes were agreed to be useful but practically difficult to implement at the present time. These included supervised toothbrushing programmes in early years settings (nurseries, playgroups etc.).

Alongside commissioning of these specific oral health programmes, there is continuing work to integrate oral health into the development of local policies for community settings and to integrate oral health into broader health improvement programmes. Professionals working in Knowsley NHS dental practices have also been encouraged to take an active role in providing preventive care and advice. Training courses to support this have historically been commissioned on a north Merseyside footprint.

**Dental Health in Knowsley**

Evidence suggests that the health of people in Knowsley (population 146,000) is generally worse compared with the average health of the population in England. Deprivation levels are higher than the national average. The Health Profile for Knowsley can be found by following this link: http://www.apho.org.uk/default.aspx?QN=HP_FINDSEARCH2012 with some more recent data available here: http://fingertips.phe.org.uk/profile/health-profiles/

The common risk factors to poor oral and dental health include unhealthy diet, smoking and harmful alcohol use. Available indicators would suggest that Knowsley compares worse than the national average for most of these risk factors.

The dental health of local populations is difficult to determine as only limited data is collected, usually related to the health of children’s teeth. Knowsley has higher than the England average % for children aged 5 with decayed, missing or filled teeth (40.3% compared to 27.9%). This is the highest on Merseyside and also higher than the North West average of 34.8%. See main report for further findings.
Dental Access in Knowsley

Child dental access rates in Knowsley are better than the England average for all ages except the 13 to 17 year old age band (Figure A), where the access rate is the same as the national rate. Adult access rates are 59.4%, which is higher than the England average of 52.0%. Research has shown\(^5\)\(^6\) that dental disease correlates closely with social and economic deprivation, meaning that usually, dental need is greater in areas of deprivation and in areas of prosperity, dental need is less.

There has been a reported seven fold difference between the populations of (former) PCTs in England with the best dental health compared to those with the worst dental health\(^7\).

Practice locations

The distance travelled to a dentist can be seen as an indicator of need and effectiveness of dental commissioning. In Map C, the red areas are the most deprived nationally, dark green the least deprived. The map shows the

\(^5\) The Office of National Statistics (1998), Adult Dental Health Survey, Oral health in the United Kingdom
\(^7\) British Association for the Study of Community Dentistry, 2003/04 survey of five-year-olds
geographical location of NHS and private dental practices mapped over the Indices of Multiple Deprivation Quintiles and how in general, the more deprived an area, the more dental practices it has. There are still areas of relative deprivation that do not have as much provision of dental practices as might be needed. Map C also plots the location of care homes in Knowsley. The dental health of vulnerable people, particularly of older people in care homes and the location of practices to care homes is an important consideration for commissioners of services. All the dental practices in Knowsley are accessible to the local population within an 8.4 minute drive. However Map D shows that there are large areas with NHS dental practices not accessible by either walking a 15 (orange) or 30 minute (yellow) distance.

Dental Practice Opening Times

The opening times of practices have an impact on how often the general population can use available dental services. Dental practices are not required to open between specific times although in most areas there are some dental practices which open outside the usual working hours of Monday-Friday 9am-6pm.

Dental Health Need Assessment
Liverpool Summary

Aims

The aims of this dental health need assessment were to determine the current health needs of the population, to investigate the current service provision for dental health in children and adults, highlighting gaps and inequalities. We also developed a set of evidence based recommendations for local commissioners on oral health promotion and prevention and for NHS England on the provision of dental health services for the local population; from Cheshire and Merseyside, through to local authority level.

********************************************************************************

Key recommendations for improving dental health in Cheshire and Merseyside

Increased provision of data
• Utilise public health and ward level data (where available) to help inform commissioning intentions and decisions.
• Explore the needs of people on low incomes but who are not exempt from dental charges.
• Undertake an additional health needs assessment into domiciliary dental care provision.

Targeted interventions
• Place oral health needs on a wider agenda for change in order for collaboration with relevant sectors and agencies to take place, for example linking with related public health programmes such as healthy eating.
• Work towards a multi-partnership oral health programme strategy for older people.
• Pursue fluoridation of public water supplies.

Improved knowledge of oral health, sharing of good practice and reporting of information
• Encourage local authorities to share good oral health practice and procedures.
• Explore tobacco cessation and alcohol awareness training for dental practices.
• Monitor NHS access to dental care at regular intervals.

********************************************************************************

Evidence of oral health promotion in Liverpool

Following the oral health promotion review in 2014, many existing programmes to prevent dental caries in children were expanded. A wide range of oral health improvement programmes have been provided across Liverpool and Sefton. These include the following:
The distribution of dental care packs including fluoride toothpaste to all children attending health visitor checks in the early years.

Supervised toothbrushing for all children attending for day care and 'wrap around' care in Liverpool and Sefton children centres.

Tailored programmes for children with additional needs - including supervised brushing with fluoride toothpaste in schools and facilitating access to early dental care and advice.

Specific work with black and minority ethnic (BME) communities to overcome barriers to accessing dental care and raise awareness of the potential effects of use of substances such as GAT in increasing the risk of mouth cancer.

Provision of a range of formal accredited training programmes for the dental team including training of dental nurses to provide preventive dental care and advice.

Provision of training to a range of key partners including health visitors, school nurses, teachers, care workers to promote dental awareness for their client groups.

Input into formal training programmes for early years workers and care workers at local FE colleges - to increase awareness of oral disease and its prevention.

Development of a 'brief intervention' model for children and families who have required removal of decayed teeth in hospital, to reduce the risk of recurrent dental decay.

Dental Health in Liverpool

Evidence suggests that the health of people in Liverpool (population 470,000) is generally worse compared with the average health of the population in England. Deprivation levels are higher than the national average. The Health Profile for Liverpool can be found by following this link: [http://www.apho.org.uk/default.aspx?QN=HP_FINDSEARCH2012](http://www.apho.org.uk/default.aspx?QN=HP_FINDSEARCH2012) with some more recent data available here: [http://fingertips.phe.org.uk/profile/health-profiles/](http://fingertips.phe.org.uk/profile/health-profiles/)

The common risk factors to poor oral and dental health include unhealthy diet, smoking and harmful alcohol use. Available indicators would suggest that Liverpool compares worse to the national average for most of these risk factors.

The dental health of local populations is difficult to determine as only limited data is collected, usually related to the health of children's teeth. In Liverpool, more than 1 in 3 (35.8%) children aged 5 have decayed, missing or filled teeth. This is higher than the England average of 27.9% and the North West average of 34.8%. See main report for further findings.

Dental Access in Liverpool

Child dental access rates in Liverpool are better than the England average for all ages except the 13 to 17 year old age band (Figure A), where the access rate is the lowest on Merseyside. Adult access rates are the lowest on Merseyside at 48.7% compared with the England average of 52.0%. All other
Merseyside areas have adult access rates higher than the national average. Research has shown that dental disease correlates closely with social and economic deprivation, meaning that usually, dental need is greater in areas of deprivation and in areas of prosperity, dental need is less.

There has been a reported seven fold difference between the populations of (former) PCTs in England with the best dental health compared to those with the worst dental health.

**Practice locations**

The distance travelled to a dentist can be seen as an indicator of need and effectiveness of dental commissioning. In Map E, the red areas are the most deprived nationally, dark green the least.

---

11. British Association for the Study of Community Dentistry, 2003/04 survey of five-year-olds
deprived. The map shows the geographical location of NHS and private dental practices mapped over the Indices of Multiple Deprivation Quintiles and how in general, the more deprived an area, the more dental practices it has. There are still areas of relative deprivation that do not have as much provision of dental practices as might be needed. **Map E** also plots the location of care homes in Liverpool. The dental health of vulnerable people, particularly of older people in care homes and the location of practices to care homes is an important consideration for commissioners of services.

All the dental practices in Liverpool are accessible to the local population within an 8.4 minute drive. **Map F** shows the majority of the Liverpool area has NHS dental practices which are accessible to either walking a 15 (orange) or 30 minute (yellow) distance. Areas towards South Liverpool including some sections of Garston and Speke cannot reasonably access dental practices by walking nor can areas to the North of the city including some areas of Gillmoss, Croxteth and Fazakerley.

**Dental Practice Opening Times**

The opening times of practices have an impact on how often the general population can use available dental services. Dental practices are not required to open between specific times although in most areas there are some dental practices which open outside the usual working hours of Monday- Friday 9am-6pm.

Dental Health Need Assessment
Sefton Summary

Aim

The aims of this dental health need assessment were to determine the current health needs of the population, to investigate the current service provision for dental health in children and adults, highlighting gaps and inequalities. We also developed a set of evidence based recommendations for local commissioners on oral health promotion and prevention and for NHS England on the provision of dental health services for the local population; from Cheshire and Merseyside, through to local authority level.

Key recommendations for improving dental health in Cheshire and Merseyside

Increased provision of data

- Utilise public health and ward level data (where available) to help inform commissioning intentions and decisions.
- Explore the needs of people on low incomes but who are not exempt from dental charges.
- Undertake an additional health needs assessment into domiciliary dental care provision.

Targeted interventions

- Place oral health needs on a wider agenda for change in order for collaboration with relevant sectors and agencies to take place, for example linking with related public health programmes such as healthy eating.
- Work towards a multi-partnership oral health programme strategy for older people.
- Pursue fluoridation of public water supplies.

Improved knowledge of oral health, sharing of good practice and reporting of information

- Encourage local authorities to share good oral health practice and procedures.
- Explore tobacco cessation and alcohol awareness training for dental practices.
- Monitor NHS access to dental care at regular intervals.

Evidence of oral health promotion in Sefton

Following the oral health promotion review in 2014, many existing programmes to prevent dental caries in children were expanded. A wide range of oral health improvement programmes have been provided across Liverpool and Sefton. These include the following:
- The distribution of dental care packs including fluoride toothpaste to all children attending health visitor checks in the early years.
- Supervised toothbrushing for all children attending for day care and ‘wrap around’ care in Liverpool and Sefton children centres.
- Tailored programmes for children with additional needs - including supervised brushing with fluoride toothpaste in schools and facilitating access to early dental care and advice.
- Specific work with black and minority ethnic (BME) communities to overcome barriers to accessing dental care and raise awareness of the potential effects of use of substances such as GAT in increasing the risk of mouth cancer.
- Provision of a range of formal accredited training programmes for the dental team including training of dental nurses to provide preventive dental care and advice.
- Provision of training to a range of key partners including health visitors, school nurses, teachers, care workers to promote dental awareness for their client groups.
- Input into formal training programmes for early years workers and care workers at local FE colleges - to increase awareness of oral disease and its prevention.
- Development of a 'brief intervention' model for children and families who have required removal of decayed teeth in hospital, to reduce the risk of recurrent dental decay.

**Dental Health in Sefton**

Evidence suggests that the general health of people in Sefton (population 274,000) is varied compared with the average health of the population in England. Deprivation levels are higher than the national average. The Health Profile for Sefton can be found by following this link: [http://www.apho.org.uk/default.aspx?QN=HP_FINDSEARCH2012](http://www.apho.org.uk/default.aspx?QN=HP_FINDSEARCH2012) with some more recent data available here: [http://fingertips.phe.org.uk/profile/health-profiles/](http://fingertips.phe.org.uk/profile/health-profiles/)

The common risk factors to poor oral and dental health include unhealthy diet, smoking and harmful alcohol use. Available indicators would suggest that Sefton compares worse than the national average for most of these risk factors.

The dental health of local populations is difficult to determine as only limited data is collected, usually related to the health of children’s teeth. In Sefton, around 1 in 4 (26.5%) children aged 5 have decayed, missing or filled teeth. Sefton is the only area on Merseyside with lower levels than the national average of 27.9%, and levels are much lower than the North West average of 34.8%. See main report for further findings.

**Dental Access in Sefton**

Child dental access rates in Sefton are better than the England average for all ages, and are the highest on Merseyside for the 13 to 17 year old age band (Figure A). Adult access rates are the
highest on Merseyside, at 63.0%, which is higher than the England average of 52.0%. Research has shown\textsuperscript{13, 14} that dental disease correlates closely with social and economic deprivation, meaning that usually, dental need is greater in areas of deprivation and in areas of prosperity, dental need is less.

There has been a reported seven fold difference between the populations of (former) PCTs in England with the best dental health compared to those with the worst dental health\textsuperscript{15}.

**Practice locations**

The distance travelled to a dentist can be seen as an indicator of need and effectiveness of dental commissioning. In Map G, the red areas are the most deprived nationally, dark

green the least deprived. The map shows the geographical location of NHS and private dental practices mapped over the Indices of Multiple Deprivation Quintiles and how in general, the more deprived an area, the more dental practices it has. There are still areas of relative deprivation that do not have as much provision of dental practices as might be needed. Map G also plots the location of care homes in Sefton. The dental health of vulnerable people, particularly of older people in care homes and the location of practices to care homes is an important consideration for commissioners of services.

All the dental practices in Sefton are accessible to the local population within an 8.4 minute drive. However Map H shows that there are large areas with NHS dental practices not accessible by either walking a 15 (orange) or 30 minute (yellow) distance.

Dental Practice

Opening Times

The opening times of practices have an impact on how often the general population can use available dental services. Dental practices are not required to open between specific times although in most areas there are some dental practices which open outside the usual working hours of Monday-Friday 9am-6pm.

Patient Satisfaction Information

The GP Patient Survey Data (2014) reports that the proportion of people in Merseyside successfully able to get an NHS dental appointment is 94% compared to 93% England average, and 53% of Merseyside report experiencing a very good overall experience compared to 48% across England.

---

16 decided to be a reasonable driving distance to access services in the recent Pharmaceutical Needs Assessment
Dental Health Need Assessment
St. Helens Summary

Aims

The aims of this dental health need assessment were to determine the current health needs of the population, to investigate the current service provision for dental health in children and adults, highlighting gaps and inequalities. We also developed a set of evidence based recommendations for local commissioners on oral health promotion and prevention and for NHS England on the provision of dental health services for the local population; from Cheshire and Merseyside, through to local authority level.

****************************************************************************************

Key recommendations for improving dental health in Cheshire and Merseyside

Increased provision of data

• Utilise public health and ward level data (where available) to help inform commissioning intentions and decisions.
• Explore the needs of people on low incomes but who are not exempt from dental charges.
• Undertake an additional health needs assessment into domiciliary dental care provision.

Targeted interventions

• Place oral health needs on a wider agenda for change in order for collaboration with relevant sectors and agencies to take place, for example linking with related public health programmes such as healthy eating.
• Work towards a multi-partnership oral health programme strategy for older people.
• Pursue fluoridation of public water supplies.

Improved knowledge of oral health, sharing of good practice and reporting of information

• Encourage local authorities to share good oral health practice and procedures.
• Explore tobacco cessation and alcohol awareness training for dental practices.
• Monitor NHS access to dental care at regular intervals.

****************************************************************************************

Evidence of oral health promotion in St. Helens

Following the oral health promotion review in 2014, many existing programmes to prevent dental caries in children were expanded. Priorities for St. Helens also include reducing inequalities in dental health of vulnerable adults. Local promotion, prevention and delivery now includes:
• Weaning advice from Health Visitors and the Health Early Years Award for nurseries are helping to make sure that young children have a healthy diet. This promotes health eating in young children.

• Brushing for life- the health visitor led programme provides oral health information, advice and a free toothbrush and toothpaste to parents of babies aged 0-3 years old (2,000 packs already distributed in quarter 1).

• In 2014 a scheme was extended to significantly increase the numbers of nurseries and children benefitting from a supervised tooth brushing programme aimed at strengthening children’s teeth using fluoride. 4,000 children currently benefit.

• All children aged 3-11 years old benefit from a free toothbrush and toothpaste 4 times per year (expanded in 2014 and now covering 9,000 children).

• Local dentists have been strengthening children teeth with fluoride varnish particularly in children who have had some teeth affected by dental decay.

• 30 nursing and care homes have received training on oral health assessment, a denture marking kit and updated policies on oral health.

• Oral health care packs and training available for carers of other vulnerable groups- YMCA, homeless charities, drug and alcohol services, carers of people with learning disabilities.

**Dental Health in St. Helens**

Evidence suggests that the health of people in St. Helens (population 176,000) is generally worse compared with the average health of the population in England. Deprivation levels are higher than the national average. The Health Profile for St. Helens can be found by following this link: [http://www.apho.org.uk/resource/browse.aspx?RID=50309](http://www.apho.org.uk/resource/browse.aspx?RID=50309) with some more recent data available here: [http://fingertips.phe.org.uk/profile/health-profiles/](http://fingertips.phe.org.uk/profile/health-profiles/)

The common risk factors to poor oral and dental health include unhealthy diet, smoking and harmful alcohol use. Available indicators would suggest that St. Helens compares worse than the national average for most of these risk factors.

The dental health of local populations is difficult to determine as only limited data is collected, usually related to the health of children’s teeth. In St. Helens, around 1 in 3 (32.9%) children aged 5 have decayed, missing or filled teeth. This is higher than the England average of 27.9%, but lower than the North West average of 34.8%. See main report for further findings.

**Dental Access in St. Helens**

Child dental access rates in St. Helens are better than those in the other local authorities across Merseyside for all ages except the 13 to 17 year old age band (Figure A). For all child age bands the rate of access is higher than the England average. Adult access rates are the second highest on
Merseyside, at 59.6% compared with the England average of 52.0%. Research has shown\(^\text{17, 18}\) that dental disease correlates closely with social and economic deprivation, meaning that usually, dental need is greater in areas of deprivation and in areas of prosperity, dental need is less.

There has been a reported seven fold difference between the populations of (former) PCTs in England with the best dental health compared to those with the worst dental health\(^\text{19}\).

**Practice locations**

The distance travelled to a dentist can be seen as an indicator of need and effectiveness of dental commissioning. In Map I, the red areas are the most deprived nationally, dark green the least deprived. The map shows the geographical location of NHS and private dental practices mapped over the Indices of Multiple Deprivation Quintiles and how in general, there is a concentration of dental practices around St. Helens town centre. To the south of the map there are areas of deprivation with no dental practices in this area. There are also areas of affluence to the

\(^\text{17}\) The Office of National Statistics (1998), Adult Dental Health Survey, Oral health in the United Kingdom
\(^\text{19}\) British Association for the Study of Community Dentistry, 2003/04 survey of five-year-olds
north west and again, there are a limited numbers of dental practices. However, all the dental practices in St. Helens are accessible to the population of St. Helens within an 8.4 minute drive. The map also plots the location of care homes in St. Helens. The dental health of vulnerable people, particularly of older people in care homes and the location of practices to care homes is an important consideration for commissioners of services.

Map J shows the NHS dental practices that can be reasonably accessed by walking 15 (orange) and 30 minutes (yellow). There are some areas in St. Helens, especially to the north west, where NHS dental practices are not accessible by walking.

**Dental Practice Opening Times**

The opening times of practices have an impact on how often the general population can use available dental services. Dental practices are not required to open between specific times although in most areas there are some dental practices which open outside the usual working hours of Monday- Friday 9am-6pm.

---
Full Report: A Dental Health Needs Assessment for Merseyside

1. Introduction to the Health Needs Assessment

Health needs assessment (HNA) is a systematic method for reviewing the health issues facing a population and the provision and adequacy of services to meet those needs. Health needs assessments can lead to agreeing priorities and resource allocation that will improve health and reduce inequalities.

Public Health is defined as: “The science and art of promoting and protecting health and wellbeing, preventing ill health and prolonging life through the organised efforts of society” (Faculty of Public Health). There are three domains of public health: health improvement (including people’s lifestyles as well as inequalities in health and the wider social influences of health), health protection (including infectious diseases, environmental hazards and emergency preparedness) and health services (including service planning, efficiency, audit and evaluation).

Why undertake a Health Needs Assessment?

A health needs assessment (HNA) is a recommended public health tool to provide evidence about a population on which to plan services and address health inequalities. It provides an opportunity to engage with specific populations and enable them to contribute to targeted service planning and resource allocation and an opportunity for cross-sectoral partnership working and developing creative and effective interventions.

A HNA also supports national and local priorities. Benefits include strengthened community involvement in decision making, improved team and partnership working, professional development of skills and experience, improved communication with other agencies and the public and better use of resources.

More detailed information on conducting a HNA can be found by following this web link below: http://www.nice.org.uk/media/150/35/Health_Needs_Assessment_A_Practical_Guide.pdf

This dental need assessment has a different scope from recent oral health need assessments, in that we focus on dental health, namely teeth and the absence or presence of decay and the reasons why some groups of people or geographical areas of Cheshire and Merseyside may have differing levels

---

of decay or disease. An oral health need assessment has a broader remit of areas to be considered such as head and neck cancers and was outside the scope for this piece of work.

However, where possible, we have endeavoured to root the background literature and the discussion of risk factors alongside the known evidence on the common risk factors of poor dental health such as sugary drinks, smoking, alcohol consumption, poor diet and income deprivation.

Figure 1a

---

Figure 1 has been developed by the Health Development Agency (2005), now, NICE, hosted by this website; http://www.urbanreproductivehealth.org/sites/mle/files/Health_Needs_Assessment_A_Practical_Guide.pdf
A Dental Health Need Assessment in Cheshire and Merseyside

Cheshire and Merseyside Public Health Intelligence group identified dental health as an issue that would benefit from further analysis via a health needs assessment. The Cheshire Dental Health Need Assessment can be found here:

Throughout this report the term Merseyside is used to describe the local authority areas of Halton, Knowsley, Liverpool, Sefton and St. Helens (see Figure 1b).

This HNA will be used to inform local commissioning arrangements for the provision of services for dental health. It will also inform local authorities’ Joint Strategic Needs Assessments (JSNAs) around the needs of the local population.

Dental services are commonly provided by both NHS dentists and private practices and a large minority of the population will pay for some private dental care. Therefore, when exploring the dental health and availability of dental services to the population it is important to consider both NHS practice and private practice availability and ideally to have a complete set of data on the dental health of the population as a whole.

However, the data on the dental health of people who attend practices that operate privately is not publicly available and cannot be accessed for this dental health need assessment. Furthermore, the availability to the local population of these practices is also unknown.

However, as part of the collection of evidence for this health need assessment Liverpool Public Health Observatory conducted a telephone survey of every registered dental practice in Cheshire and Merseyside as listed on the Care Quality Commission website. We asked practices to provide us with information about opening times, whether the practice had a NHS contract or was fully private for adult patients, whether they were currently accepting new NHS adult patients and for how long a patient would usually have to wait to be seen for a routine appointment. The results of this survey are in chapter 8.

Engagement at the local and senior level is crucial to the success of any health needs assessments including dental and oral health need assessments. Professional stakeholders are important people to involve from the outset of the process to ensure sponsorship by those people with the power to make the necessary decisions for change if required. During this dental health need assessment we engaged and worked with a variety of professional stakeholders including local authority public
health leads, managers and information specialists, assistant director of public health, an academic professor from a local university, local authority commissioners, public health consultants and Public Health England (PHE) consultants in dental public health. Professionals from across the Cheshire and Merseyside area in these roles were consulted on a regular basis and provided ongoing support to the researchers.

**Strengths of this Dental Health Need Assessment in Cheshire and Merseyside**

- A good breadth and depth of literature was sourced to inform the background and literature gathering for this Dental Health Need Assessment.
- Our steering group for the project included professionals from a variety of backgrounds and working across areas all related to dental health and public health information.
- Primary data was collected from every practice in Cheshire and Merseyside in an attempt to map the current availability of NHS dental services in Cheshire and Merseyside and at Local Authority levels.

**Limitations of this Dental Health Need Assessment in Cheshire and Merseyside**

- Data from private dental practices is not included and therefore the true use and availability of dental services is likely to be under reported and the rate of decay amongst adults over reported.
- The scope of this dental health needs assessment is limited; our timescale was short and primary research data was not collected until near the end of the project.
- The timescale and resources did not allow us to work with patient or public groups as would be expected in a comprehensive health need assessment.
- The findings and recommendations of this report can only be applied to the provision of NHS dental health services and to NHS patients.

**Aims of this dental health needs assessment**

1. To determine the current health needs of the population in relation to dental health in Merseyside for NHS patients.
2. To investigate the current service provision for dental health in children and adults highlighting any gaps and inequalities based on the new dental contract.
3. To make a set of evidence based recommendations for local commissioners on the provision of oral health promotion for the local population.
Figure 1b

The area of Merseyside has been defined as the following local authorities:
2. Headline findings and recommendations

- Dental health across Cheshire and Merseyside is varied. People across Merseyside have more routine treatments than the England average, especially in Liverpool. People in Merseyside have a much greater uptake for complex dental work, than would be expected, particularly in Knowsley and Liverpool.

- The level of deprivation is linked to the complexity of the treatment, with more deprived children needing more complex and urgent treatment than those in more affluent groups.

- Units of Dental Activity (UDA) claimed for each patient is a fundamental measure of the intensity of resource use. The UDA per child patient in Merseyside is higher than the England average.

- On average, 3 year olds in England have 11.7% of their teeth decayed, missing or filled, with a North West average of 14.3%. Local authorities in Merseyside were below national and North West levels: Halton 10.3%; Knowsley 10.5%; Liverpool 11.0%; Sefton 10.2%; St. Helens 10.2%. However at age 5, all Merseyside areas except Sefton were above the national level of 27.9% children with decayed, missing or filled teeth. In Knowsley and Liverpool, levels were also above the North West average of 34.8%.

- LPHO conducted a telephone survey and found that, in Merseyside, almost three quarters (74%) of NHS dental practices had some out of hour’s weekday access, but only 1 in 10 (10.1%) on a Saturday. Of NHS dental practices, 1 in 4 (25.8%) had expected routine appointment waiting times of more than 2 weeks. Of all practices, 75% hold NHS contracts for adults and of these, approximately 71.3% were currently accepting new NHS adult patients.

This dental health need assessment has highlighted a number of areas that merit development across Cheshire and Merseyside;

- Local authorities should look for ways to share good practice and successful health promotion and illness prevention ideas.
- Gaps in the NHS dental services have been highlighted and need addressing.
- To achieve this, regular, comprehensive dental health need assessments would enable us to look at the needs of the population at local authority and local area level and should be
undertaken every three years on a rolling, staggered basis, if costs of a general population HNA are prohibitive e.g. Year 1: Children, Year 2: Working Age People, Year 3: Older People.

- Dental health should be included in the Joint Strategic Needs Assessment process.

In collaboration between LPHO as the project document authors, the local authority and Public Health England steering group members and University of Liverpool academic colleagues, it was decided that the list below represented the key recommendations from this report:

### Increased provision of data

- **Recommendation 1:** Public Health and ward level data (where available) should be utilised to help inform commissioning intentions and decisions. The continued commissioning of the dental epidemiology programme is essential and a full census survey on the oral health of children, adults and older people could be considered in order to provide ward level data which would enable further detailed understanding of the needs of vulnerable groups in the population. This would improve the data available to local authorities and the region.

  **Action:** Currently, Public Health England develop the national programme for dental epidemiology surveys, commissioned by local authorities. It is expected that in the future, local authorities will be more involved in setting the national dental epidemiology programme. They may also wish to commission their own local survey work to support needs assessment, or may wish to augment sample survey work (set out in the national programme) to census based surveys. A staggered approach to a census survey, with a yearly rolling remit of children, adults and older people, could be explored by local authorities.

- **Recommendation 2:** Explore the needs of people on low incomes but who are not exempt from dental charges. Currently, 700,000 people are on zero hour contracts- costs may hinder access to preventive care.

  **Action:** Commission research to explore the experience of people who do not qualify for exemption, but who are on low incomes. This could be led by the local authority in collaboration with the Knowledge and Intelligence Teams within PHE.

- **Recommendation 3:** The level of domiciliary care provision was outside the scope of this DHNA.
Action: Further research is required to investigate domiciliary care provision and whether it is appropriate for the populations’ need.

**Targeted interventions**

- **Recommendation 4:** Oral health needs to be placed on a wider agenda for change in order for collaboration with relevant sectors and agencies to take place. One suggestion could be an 'oral health promoter' post for someone to have dedicated time to provide oral health promotion services to priority population groups and to provide a full range of oral health promotion and preventative advice across the whole life course. The post could link with related public health programmes such as healthy eating.

  **Action:** Adopt a common risk factor approach in developing dental health promotion including promoting self-care management across all health and social care settings for example, “making every contact count”.

- **Recommendation 5:** Work towards a multi-partnership oral health programme strategy for older people.

  **Action:** Public health teams within local authorities, in partnership with NHS England and supported by Public Health England, should lead the development of an oral health strategy by 2016, with a focus on prevention, promotion and appropriate treatment for older people. This work should be underpinned by oral health needs assessment.

- **Recommendation 6:** Pursue fluoridation of public water supplies.

  **Action:** Public Health England

**Improved knowledge of oral health, sharing of good practice and reporting of information**

- **Recommendation 7:** Encourage local authorities to share good oral health practice and procedures, targeted interventions and local preventative and promotion strategies to improve health of the wider geographical footprint.

  **Action:** Local Authority Public Health Teams should utilise existing Public Health networks to facilitate the sharing of best practice among partners.
• **Recommendation 8:** Explore tobacco cessation and alcohol awareness training for dental practices.

**Action:** Local Authority Public Health Teams should explore training opportunities relating to tobacco cessation and alcohol awareness for all staff within dental practices, on an on-going basis.

• **Recommendation 9:** Monitor NHS access to dental care at regular intervals, to assess trends of e.g. access to NHS dentists. Access should always be at a reasonable level (to be defined).

**Action:** NHS England or PHE could report to Health and Wellbeing Boards on an annual basis.
3. Background literature

Oral health is a state of being “free from mouth and facial pain, oral and throat cancer, oral infection and sores, periodontal (gum) disease, tooth decay, tooth loss and other disorders and diseases that limit a person’s capacity in biting, chewing, smiling, speaking and psychosocial wellbeing”\(^{23}\).

Oral health is an integral part of general health with a range of conditions such as obesity, stroke, cancers, diabetes, sharing with oral health a set of common risk factors such as: diet, smoking, and alcohol. Oral diseases include dental caries, periodontal disease, oral mucosal lesions, oropharyngeal cancer, HIV/AIDS related oral diseases and orodental trauma.

Oral diseases are often linked to chronic disease (CVD, cancers, chronic respiratory disease and diabetes). Poor oral hygiene is also a risk factor for oral disease. Oral diseases include dental caries, periodontal disease, tooth loss, oral mucosal lesion, oropharyngeal cancer, HIV/AIDS related oral diseases and orodental trauma and are major public health problems.

**Dental health history in the UK\(^ {24}\)**

In the early 1900s dental health in England was very poor. Many people had no teeth and dental decay was universal. Urbanisation had led to less consumption of fresh foods and there had been a huge rise in the amount of sugar eaten - a five times increase. The first known dental survey was undertaken in 1893 and began the interest in paediatric dentistry - it also reflected British society by examining children across different social classes. See Fig 1.

Until the NHS was founded in 1948, fillings were not commonly used; they were too expensive for most people. As people started to use the dentist more frequently, there was a surge in demand for dental care and after 3 years, in 1951 the government introduced charges for dental treatment. The escalation of demand was not met by an increase in dentists, despite the increase in demand having the potential to significantly increase dentist’s earnings. Since then, NHS dental charges for adults have remained, increasing at various rates over time.

This new system of providing dental treatment didn’t bring improved techniques or equipment and inadequate local anaesthetic often made visiting the dentist unpleasant. In 1959 there was a revolution in the area of caring for teeth at home as fluoride toothpaste was first marketed in the UK. By 1980 96% of toothpaste contained fluoride and dentate adults going for regular check-ups rose from 43% to 59% in 1998. Table 1 shows the relative liability to dental caries in poor and high

When the first adult survey of dental health was published in 1968 over a third of the adult population had lost their teeth. Of these people 7% were aged 25-34 and 22% aged 35-44. These young edentate adults of 1968 are now part of an older generation whose overall levels of tooth retention are an important consideration when evaluating the oral health of the population in the 2009 national Adult Dental Health Survey. By 1978 there was a change in the nature of how disease and decay was treated meaning that people were gradually having their teeth filled rather than extracted.

The demand for healthy and beautiful teeth has developed in recent years as the public become more image-conscious and people become more willing to pay for their treatment. The proportion of people having private dental treatment nationally has risen in recent years.

**Groups in society who are more at risk of poor dental health**

By 1998 published research studies had shown that it was clear that there are certain groups of people who are at a higher risk of poor dental health and therefore increased risk of gum disease and tooth decay than others. These are identified as;

1. Older age groups (past the age of retirement), dominated by those with no teeth at all and in need of complete dentures.
2. A young generation (under the age of 30), with a low need for fillings, likely to stay healthy as long as preventive care is available.

---

3. A group between 30 and 65 years old who had previously experienced a high level of disease which had been treated by fillings and who will have high maintenance needs as they age.\textsuperscript{26}

4. Other at risk groups include people with disability, those in long term institutional care (prisons, care homes and psychiatric hospitals), homeless people, refugees and asylum seekers, some BME groups.

5. In children, although dental health is amongst the best in Europe, there is a higher risk of poor dental health amongst those in the low socioeconomic groups (50% higher in low SES groups when compared to high SES groups).\textsuperscript{27}

Poor dental health can be associated with a number of other problems which can limit a person’s quality of life:

<table>
<thead>
<tr>
<th>Good dental health can lead to.....</th>
<th>Poor dental health can lead to.....</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>The ability to communicate effectively</td>
<td>Sleepless nights and pain and discomfort</td>
</tr>
<tr>
<td>A contribution to an attractive appearance</td>
<td>Infection</td>
</tr>
</tbody>
</table>

**Socioeconomic variation in dental health**

We know from research that socioeconomic variations in health exist and two pivotal independent UK health inquiries, the Acheson\textsuperscript{28} and Black\textsuperscript{29} reports, helped generate extensive debate on inequalities in health, informing policy and action. Dahlgren and Whitehead (1991) developed a framework that identifies how a range of different factors can impact on personal and community health (Figure 1c). Whilst an individual has no control over his or her age, sex and genetics, wider determinants of health can affect the likelihood of a person developing a disease, or in dying prematurely. Such determinants of health include:

1. Individual lifestyle factors: e.g. diet, physical activity, smoking, alcohol, drugs, behaviour.
2. Social and community factors: e.g. crime, unemployment, social exclusion, local cultures.
3. Living and working conditions: e.g. housing and air or water quality.

4. General socio-economic factors impacting on health: e.g. poverty and income, economy.

Figure 1c

The understanding of these determinants of health has since been developed, particularly with a focus towards the health inequalities across and within regions of England. In the Due North report published in September 2014, the Inquiry’s overarching assessment of the main causes of the observed problem of health inequalities within and between North and South are:

- Differences in poverty, power and resources needed for health;
- Differences in exposure to health damaging environments, such as poorer living and working conditions and unemployment;
- Differences in the chronic disease and disability left by the historical legacy of heavy industry and its decline;
- Differences in opportunities to enjoy positive health factors and protective conditions that help maintain health, such as good quality early years education; economic and food security, control over decisions that affect your life; social support and feeling part of the society in which you live.

The life course perspective is of fundamental importance in terms of explaining how health inequalities are created. Other components include; socio-political contexts, structural determinants and socioeconomic position and intermediary determinants. Figure 1d below illustrates how

---

different areas for action for communities have varying influences on an individual at different points in their life.

**Figure 1d: Life course stages and entry points for impacting health**

Austerity measures and their impact on dental health

Not only are there strong step-wise gradients in these root causes, but austerity measures in recent years have been making the situation worse – the burden of local authority cuts and welfare reforms has fallen more heavily on the North than the South; on disadvantaged than more affluent areas; and on the more vulnerable population groups in society, such as children. These measures are leading to reductions in the services that support health and well-being in the very places and groups where need is the greatest.
In general, people living in areas of material and social deprivation are more likely to have poor dental health and higher levels of tooth decay than those living in more affluent areas. There are well know factors which link people living in poverty to a range of health problems, the most common being coronary heart disease and stroke. Some of these include; poor general living conditions, difficult access to health care services, low education level and poor work environment, poor quality housing and unhealthy food choices are some of the factors.

A major research evidence finding is that oral diseases are not merely different at the extremes of society, that is between the most affluent and most deprived, but that oral diseases, as is the case with other health outcomes are socially patterned across the entire social hierarchy; a relationship known as the social gradient.

Health status, including oral health, is directly related to the socioeconomic position across the socioeconomic gradient in populations and those in higher social ranks are healthier than those immediately below them in a stepwise and consistent nature. Figure 1e shows the relationship between the occupational position of someone as an indicator for their social position, and the number of teeth they have. The more affluent a person, measured in the graph below by occupational group the person occupies, the less likely they are to have no natural teeth. The more ‘routine’ the occupation, the more likely they are to be edentate.

Figure 1e: Social Gradient in Oral Health (source, Watt and Sheiham 2012)

---

Evidence from Sheiham and Watt\textsuperscript{32} shows that a main cause of inequalities in oral health are differences in the patterns of consumption of non milk extrinsic sugars and fluoridated toothpaste and that improvements over time have largely occurred due to social, economic and environmental factors alongside fluoridation toothpaste. There is evidence to suggest that people in lower socioeconomic groups are more likely to have diets high in sugary foods and drinks and they brush their teeth less often. The frequent and high consumption of sugars is the main cause of dental decay and a range of factors influence what people eat and drink including costs, availability, access, clear information and knowledge or education level\textsuperscript{33}. Other factors which are associated with poor dental health (and poor general health) include smoking and alcohol consumption- both more prevalent in lower SES groups. Smoking and excessive alcohol consumptions are also risks to developing gum disease and oral cancer and evidence shows that heavy drinkers and smokers are 30 times more likely to develop oral cancer than non smokers and non drinkers\textsuperscript{34}.

The 2003 National Survey of Child Dental Health highlights inequalities by socioeconomic group and how there is a 50% increase in obvious decay amongst the lowest SES group and the highest. At an individual level and when comparing children who have decay, there is evidence that more teeth are likely to be decayed in low SES groups than in higher SES group and further, clearer evidence that treatment choices may be affected, with extraction of permanent teeth much more likely in deprived groups.

The British Dental Journal published a paper called, ‘Oral diseases and socio-economic status’\textsuperscript{35} and findings suggested that the association between SES status and oral and dental health should be taken into consideration when developing health promoting policies.

**Primary Care and Financial Challenges**

Dentistry is predominately a primary care service with NHS dental services provided in primary care and community settings. The primary care dental team is diverse and includes; dentists, dental therapists, dental hygienists, dental technicians, clinical dental technicians and dental nurses. Starfield\textsuperscript{36} identified four cardinal features of primary care:

\textsuperscript{34} Blot, WJ (1988) Smoking and drinking in relation to oral and pharyngeal cancer \url{http://cancerres.aacrjournals.org/content/48/11/3282.long}
\textsuperscript{35} Hobdell, M.H et.al. (2003) \url{http://www.nature.com/bdj/journal/v194/n2/pdf/4809882a.pdf}
\textsuperscript{36} Starfield B. Is primary care essential? Lancet 1994; 344: 1129-1133
1. First contact between the healthcare system and members of the public.
2. Ongoing, person centred care over time.
3. Comprehensiveness-addressing all of the commonly encountered needs of the population.
4. Co-ordination or integration-referral to specialist for patients who have an unusual or uncommon conditions.

Whilst on the one hand being asked to make financial savings, at the same time, primary care is being expected to provide more personalised, accessing community based services for patients, particularly older people and those with multiple long term conditions

There are over 1 million patient contacts with NHS dental services each week. Dentists working in general dental practices are not NHS employees. They are independent providers from whom the NHS commissions services. It is common for dental practices to offer both NHS funded and private services.

- £3.4 billion per year is spent by NHS England on dental services.
- £2.3 billion per year is spent by the private market on dental services.
- £653 million in 2013 came from the dental charges system (all adult patients make a financial contribution for receiving dental care from the NHS unless they meet certain exemptions) into the NHS budget.
- Primary care services, like other parts of the NHS, face a challenge to close the projected 2021/22 funding gap of £30 billion.
- Financial inefficiencies could be reduced and better value for money secured.

Preventive oral health programmes have the potential for savings, such as the national Childsmile programme in Scotland. The Faculty of Dental Surgery (FDS) noted that the Scottish programme resulted in savings of more than £6 million in children’s dental treatment over a nine year period from 2001-02, mainly owing to fewer tooth extractions, fillings and general anaesthetics. NHS costs associated with the dental disease of five-year olds decreased dramatically, with savings from the programme far outweighing the costs.

---

National Policy and Dentistry

Following the Darzi report, there was a call for quality to be a key ‘organising principle of the NHS’ and the current government’s 2010 NHS White Paper sought to promote a “patient focused, clinically led, outcomes driven NHS”. The NHS constitution, supported and updated by the current government, lists as one of its seven guiding principles: ‘The NHS aspires to the highest standards of excellence and professionalism in the provision of high quality care that is safe, effective and focused on patient experience’.

In England, the first steps have been taken to incentivise quality in the development of a Dental Quality and Outcomes Framework (DQOF, 2011), involving pilots for a new dental contract. Improving oral health is one of the DQOF main objectives, using a care pathway approach to provide a dental service that helps people maintain good oral health, not one that is focused on treatment only. The DQOF is a voluntary incentive scheme, rewarding dentists for how well they care for patients. It will measure the quality of their work, and the clinical outcomes they achieve, ‘providing a better way of holding them to account than simply measuring the number of UDAs they carry out’ (p.4, DQOF). The DQOF is being tried out in 94 pilot dental practices, with early findings showing that dental teams are putting a firm focus on more preventative dental care.

With the publication in 2014 of ‘Improving dental care and oral Health - a call for action’, the government made a commitment to oral health and dentistry with a drive to:

- Increase the oral health of the population, particularly for children
- Introduce the new NHS primary dental care contract
- Increase access to NHS primary care dental services

The new responsibilities of the Local Authority

The dental public health functions of local authorities are described in the 2012 regulations for NHS bodies and Local Authorities \(^{48}\) and are outlined in the 2014 Public Health England (PHE) document ‘Tackling Poor Oral Health in Children’\(^{49}\): Under the terms of the Health and Social Care Act (2012), upper tier and unitary local authorities became responsible for improving the health, including the oral health, of their populations from April 2013. There is a statutory requirement for local authorities to provide or commission oral health improvement programmes and oral health surveys. The surveys have the following functions:

- assessment and monitoring of oral health needs
- planning and evaluation of oral health promotion programmes
- planning and evaluation of the arrangements for the provision of dental services
- reporting and monitoring of the effects of any local water fluoridation schemes covering their area.

Additionally, local authorities also have the power to make proposals regarding water fluoridation schemes and a duty to conduct public consultations in relation to such proposals. They have powers to make decisions about such proposals\(^{50}\). A recent Public Health England (PHE) report found that 45% fewer children aged 1 to 4 in fluoridated areas are admitted to hospital for tooth decay\(^{51}\). Water fluoridation schemes were found to exist in 15 out of 152 local authorities. The Faculty of Dental Surgery (FDS) would like to see the government encourage all local authorities to introduce such schemes, which would help to reduce the significant inequalities in children’s oral health across the country\(^{52}\).

The role of local government will soon also be extended to include commissioning responsibility for the Healthy Child Programme for 0-5 year olds, which will transfer from NHS England to local government from 1 October 2015. This will include the commissioning of health visitors who lead

---

\(^{48}\) The NHS Bodies and Local Authorities (Partnership Arrangements, Care Trusts, Public Health and Local Healthwatch) Regulations 2012; Statutory Instrument No.3094, Part 4; page 8
http://www.legislation.gov.uk/uksi/2012/3094/made

and support delivery of preventive programmes for infants and children, including providing advice on oral health and on breastfeeding, reducing the risk of tooth decay.

**Recent guidance promoting dental health**

Public Health Outcome Framework (2013-16) domain 4 includes an indicator related to ‘tooth decay in children under 5 years old’

The 2012 Public Health Outcome Framework (2013-16)\(^{53}\) domain 4 includes an indicator related to ‘tooth decay in 5 year old children’. The objective is to reduce the numbers with tooth decay whilst also reducing the gap between communities. The British Dental Association (BDA)\(^{54}\) suggested that it will promote collaborative working between health and social care professionals locally, and between family members around the establishment of good diet and effective oral hygiene routines, and welcomed the focus the indicator gives to evidence-based interventions to reduce avoidable ill-health and inequalities. Local authorities can use this indicator to monitor and evaluate children’s oral health improvement programmes in the long term. One suggestion for further implementation is that the BDA would like to see a further oral health indicator relating to older age groups, which would also encourage local partnerships across health and social care.

**NHS Outcomes Framework 2014-15**\(^{55}\) includes indicators related to patient experience of NHS dental services and access to NHS dental services, both Domain 4 indicators: ‘Ensuring that people have a positive experience of care’.

Domain 3 indicators relate to ‘Helping people to recover from episodes of ill health or following injury’. These have been extended to include additional dental indicators relating to:

- the proportion of people with decaying teeth and
- the number of tooth extractions in secondary care for children under ten years old\(^{56}\).

---

The toolkit provides guidance to dental teams on oral health assessments, age-appropriate preventive advice, and the use of toothpaste with high concentrations of fluoride. This has been welcomed by the Faculty of Dental Surgery (FDS)58 who note that, along with the new dental contract, these initiatives will support children and their parents to follow advice and encourage dentists to identify children at high caries risk, with the focus shifting towards preventive action.

The second edition of the Public Health England publication ‘Smokefree and Smiling’ provides updated guidance for dental teams, commissioners and educators on how they can contribute to reducing rates of tobacco use, and highlights resources available to support them. It will help dental teams to play a supportive role in encouraging patients who use tobacco to quit improving their general and oral health59.

The Children and Young People’s Health Outcome Forum report was published in 201260 and their annual report in 201461, both recommending that important integration and greater action should be taken to reduce the regional variation in child health outcomes.

The NHS Outcomes Framework 2014-15 includes indicators related to;

- Patient experiences of NHS dental services
- Access to NHS dental services

NICE guidelines

The NICE guideline on ‘Oral health: approaches for local authorities and their partners to improve the oral health of their communities’ was published in October 2014. It makes recommendations on undertaking oral health needs assessments, developing a local strategy on oral health and delivering

---

community-based interventions and activities. It suggests that local authorities in England should ensure all early years’ services provide oral health information and advice. The FDS note that this builds on the important PHE toolkit for local authorities and includes recommendations for supervised tooth brushing and fluoride varnishing programmes in nurseries and primary schools in areas where children are at high risk of poor oral health. However, the FDS are concerned that many local authorities with reduced funding will ignore this advice. They recommend that the government needs to invest in a national oral health programme, such as in Scotland and Wales, which has resulted in reduced oral inequalities and improved access to dental services for children, saving the NHS millions in children’s dental treatment (see p.17).

The NHS England ‘Improving Dental Care and Oral Health- A Call to Action’ 2014 report mentions the following key points and recommendations:

1. There is a wide variation of disease across England.
2. Levels of oral diseases are highest in the most deprived areas.
3. Concerns about NHS dental charges can be a very real barrier for those on a low income. Clear information to patients that explains the dental charges system and what help is available is important to ensure patients are not discouraged from seeking the dental care they need.
4. Although some ethnic groups are known to have a higher prevalence of certain oral diseases, they are less likely to access NHS dental services.
5. Domiciliary services need to be available to all.
6. Some patients are reluctant to access dental services- they may not see it as a priority, be afraid or for cultural reasons not see regular dental care as a priority.
7. Overcoming the barriers that this ‘seldom heard’ group face in accessing care needs to be a key part of the approach to commissioning future dental services if we want to improve access and outcomes for all.

Evidence for targeted inventions to reduce health inequalities

---

To summarise, they conclude that strategies to tackle social inequality in oral health should focus on reducing the angle of the social gradient (as seen in Figure 2 on the right hand side). Based on the principle of proportionate universality, the oral health commissioners should apply population strategies tackling the upstream causes of oral health inequalities e.g. actions directed at the unregulated activities of the manufacturers and distributors of processed sugary products. Intermediate oral health policies could focus on developing supportive oral health environments in a variety of settings such as schools, colleges, hospitals, workplaces and care organisations. From a life course perspective it is important how preschool settings that ensure a supportive early life environment are created and nurtured.

Figure 2: New conceptual model for oral health inequalities (Watt and Sheiham, 2012)

“Integrating the common risk factor approach into a social determinants framework”

The concept of the common risk factor approach (CRFA) was based on health policy recommendations from the WHO in the 1980s that encouraged an integrated approach to chronic disease prevention. In 2000 the general concept was extended to include oral conditions. Researchers have critically updated the common risk factor approach (CRFA) based on research and policy developments on reducing health inequalities, showing that policies to tackle structural determinants should be included in interventions.
4. Overview of the data used in the Dental Health Need Assessment for Merseyside

The majority of the ‘activity data’ presented in this report was obtained from the Business Services Authority. The data covers the time periods of:

- For activity data: 2013/14 performance year (as at March 2014)
- For access and distances: 24 month period\(^{64}\) up to March 2014.

Activity data is based on the patients’ local authority, based on home postcode as entered on FP17\(^{65}\). Data is based on the local authority where a patient is resident, irrespective of where the treatment took place.

The majority of the ‘need’ data, or the data that tells us the story about people and their dental health, at a national and sometimes North West, Merseyside or ward level, is from the Child Dental Survey (2003) or the Adult Dental Health Survey (2009).

The 2003 Children’s Dental Health Survey, commissioned by the four United Kingdom Health Departments and undertaken by the Office for National Statistics, is the fourth in a series of national dental surveys carried out every 10 years since 1973\(^{66}\). The survey covers a representative sample of children at the ages of five, eight, twelve and fifteen years attending state and independent schools in the U.K. in 2003 12,658 children were sampled and a total of 10,386 children were examined which achieved an 82% response rate. The most recent survey results for 2013 had not yet been released at the time of writing this report. Some information for specific age groups has been released; for example the results for 5 year olds for 2011/12 have been released. Wherever possible, throughout the report, the most recently available data will be reported.

The main purpose of the Adult Dental Health Survey is to get a picture of dental health of the adult population and how this has changed over time; it has been carried out every 10 years since 1968\(^{67}\). The aims of the survey are to investigate dental experiences, knowledge about and attitude towards

\(^{64}\) This is based on guidelines from NICE which recommend the longest period between oral reviews for adults is 24 months.

\(^{65}\) Providers (usually dental practices) submit forms to the NHS detailing dental activity data. The data recorded on the FP17 shows the patient charge collected, the number of units of activity performed and treatment banding information.

\(^{67}\) [http://www.hscic.gov.uk/pubs/dentalsurveyfullreport09](http://www.hscic.gov.uk/pubs/dentalsurveyfullreport09)
dental care and oral hygiene; to examine changes over time in dental health, attitudes and behaviour; and to monitor the extent to which dental health targets set by the Government are being met. It is the largest epidemiological survey of adult dental health in the UK; a total of 11,380 individuals were examined and 6,469 dentate adults were examined. The summary of the report of the ADHS (2009) can be accessed here: [http://www.hscic.gov.uk/catalogue/PUB01086/adult-dent-heal-surv-summ-them-exec-2009-rep2.pdf](http://www.hscic.gov.uk/catalogue/PUB01086/adult-dent-heal-surv-summ-them-exec-2009-rep2.pdf).

Other sources of information will be used to inform this Dental Health Need Assessment;

- Data will be used from organisations such as the Care Quality Commission to enable exploration of locations of dental practices, out of hour’s services and domiciliary services.
- Data from NHS England local area teams to explore what treatment is referred to specialist services, the nature of local complaints about dental care and access and whether dental practices are disability compliant.
- Local authority evidence of good practice in their locality and services including audits and schemes that have been running locally.
- Finally, a telephone survey was conducted with all CQC listed dental practices in Cheshire and Merseyside approximately 230 in Merseyside and 200 in Cheshire. Each practice was asked to provide information about waiting times, the availability for new NHS patients to register, the usual wait time for a routine appointment and whether the practice was open out of hours.

The Dental Health Needs Assessment will outline the background literature and the national policy perspective of dentistry and dental health. This includes a focus on children’s dental health, adult’s dental health and the dental health of vulnerable people in Merseyside. The following are explored:

- Dental Health- the health of the Merseyside population, including children and adults.
- Dental Availability- availability of and access to dental care treatment, related issues.
- Vulnerable population groups- BME groups, Learning disabled people, Homeless people, Prisoners, and Older people.
5. Overall Health in Merseyside Local Authorities

Evidence suggests that general health profiles are indicative of dental health profiles for geographical and socioeconomic areas in England. As with general health, there are many factors which contribute to the variation in dental health across the UK including:

- Socioeconomic factors.
- Geographical differences in service provision.
- Access to services for the general population
- Access to services for vulnerable groups including language or cultural barriers for BME groups, people in institutions or homeless people who cannot regularly access services and people with learning disabilities, or elderly people who have complex and multiple health and social care needs.

Merseyside has more risk factors for poor general health as well as poor dental health than other areas of the UK. The most recent ‘Health Profiles’ published by PHE were available from July 2014 and can be found, by local authority, here: [http://www.apho.org.uk/default.aspx?RID=49802](http://www.apho.org.uk/default.aspx?RID=49802)

Public Health England\(^68\) (PHE) publishes ‘Health Profiles’\(^69\) for every local authority in England. These Health Profiles are designed to help local government and health services identify problems in their areas and decide how to tackle them. They provide a snapshot of the overall health of the local population, and highlight potential problems through comparison with other areas and with the national average. The Health Profiles programme is part of Public Health England, an executive agency of the Department of Health.

The profiles are produced at local authority level because they are intended for use by elected councillors, directors of public health, council officers and other members of the Joint Strategic

---

\(^68\) Public Health England was established on 1st April 2013 to protect and improve the nation’s health and wellbeing and to reduce inequalities. It will lead on the development of a 21st century health and wellbeing service, supporting local authorities and the NHS to deliver the greatest possible improvements in public health

\(^69\) Each Health Profile document includes: An ‘At a glance’ summary description of people’s health in the area/ Maps and charts that show how the health in the area compares to the national and local view/ Trended information showing changes in death rates over a ten year period of time/A ‘spine chart’ health summary showing the difference in health between the area and the average for England for 32 indicators
Needs Assessment (JSNA) process, and by members of the Health and Wellbeing Boards. Health Profiles are now an established part of planning for health improvement.

Common risk factors related to general dental health such as deprivation, diet and obesity, alcohol use and smoking as well as general life expectancy have been highlighted in the summaries below. For other health related statistics and information please see the full version of the summary by following the links provided.

**Halton 2014 Health Profile Summary**

The health of people in Halton (population 126,000) is generally worse than the England average. Some headlines taken from the PHE health profiles and updates are:

- Deprivation and child poverty are higher than average, with 25.6% (6,370) of children living in poverty.
- Life expectancy for both men and women is lower than the England average. Life expectancy is 8.9 years lower for men and 8 years lower for women in the most deprived areas of Halton than in the least deprived areas.
- Estimated levels of adults with excess weight (70.2% overweight or obese) and obesity (35.2%) are worse than the England average. In Year 6, 21.1% (265) of children are classified as obese, similar to the average for England.
- The rate of alcohol specific hospital stays among those under 18 is 73.5 per 100,000, worse than the average for England. This represents 62 stays per year. The rate of alcohol related harm hospital stays amongst adults is 814 per 100,000, worse than the average for England. This represents 987 stays per year.
- Levels of breastfeeding and smoking at time of delivery are worse than the England average.
- Smoking prevalence is 18.4%, similar to the England average. The rate of smoking related deaths is 416 per 100,000 aged 35+, worse than the average for England. This represents 758 deaths per year.

The complete health profile and updates can be found by following these links:

- [http://fingertips.phe.org.uk/profile/health-profiles/data](http://fingertips.phe.org.uk/profile/health-profiles/data)

**Knowsley 2014 Health Profile Summary**

The health of the people in Knowsley (population 146,000) is generally worse than the England average. Some headlines taken from the PHE health profiles and updates are:
Deprivation and child poverty are higher than average, with 30.0% (9,295) of children living in poverty.

Life expectancy for both men and women is lower than the England average. Life expectancy is 9.7 years lower for men and 7.8 years lower for women in the most deprived areas of Knowsley than in the least deprived areas.

Estimated levels of adults with excess weight (67.3% overweight or obese) and obesity (23.4%) are similar to the England average. In Year 6, 23.1% (370) of children are classified as obese, worse than the average for England.

The rate of alcohol specific hospital stays among those under 18 is 65.1 per 100,000, worse than the average for England. This represents 64 stays per year. The rate of adult alcohol related harm hospital stays is 859 per 100,000, worse than the average for England. This represents 1,205 stays per year.

Levels of smoking at time of delivery are worse than the England average.

The prevalence of smoking is 23.4%, which is higher than the England average. The rate of smoking related deaths is 444.5 per 100,000 aged 35+, worse than the average for England. This represents 1,001 deaths per year.

The complete health profile and updates can be found by following these links:

http://fingertips.phe.org.uk/profile/health-profiles/data

Liverpool 2014 Health Profile Summary

The health of the people in Liverpool (population 470,000) is generally worse than the England average. Some headlines taken from the PHE health profiles and updates are:

Deprivation and child poverty are higher than average, with 32% (25,335) of children living in poverty.

Life expectancy for both men and women is lower than the England average. Life expectancy is 10 years lower for men and 9 years lower for women in the most deprived areas of Liverpool than in the least deprived areas.

Estimated levels of adults with excess weight (67.2% overweight or obese) and obesity (25.9%) are similar to the England average. In Year 6, 23.7% (937) of children are classified as obese, worse than the average for England.

The rate of alcohol specific hospital stays among those under 18 is 86.4 per 100,000, worse than the average for England. This represents 231 stays per year. The rate of adult alcohol
related harm hospital stays is 810 per 100,000, worse than the average for England. This represents 3,510 stays per year.

- Levels of breastfeeding and smoking at time of delivery are worse than the England average.
- Prevalence of smoking is 22.9%, which is higher than the England average. The rate of smoking related deaths was 448.3 per 100,000 aged 35+, worse than the average for England. This represents 2,876 deaths per year.

The complete health profile and updates can be found by following these links:
http://fingertips.phe.org.uk/profile/health-profiles/data

Sefton 2014 Health Profile Summary
The health of the people in Sefton (population 274,000) is varied compared to the England average. Some headlines taken from the PHE health profiles and updates are:

- Deprivation and child poverty are higher than average, with about 20.1% (9,340) children living in poverty.
- Life expectancy for men but not for women is lower than the England average. Life expectancy is 12 years lower for men and 10.5 years lower for women in the most deprived areas of Sefton than in the least deprived areas.
- Estimated levels of adults with excess weight (68.7% overweight or obese) are higher than the England average. Levels of obesity (23.6%) are similar to the England average. In Year 6, 19.6% (537) of children are classified as obese, similar to the average for England.
- The rate of alcohol specific hospital stays among those under 18 is 78.1 per 100,000, worse than the average for England. This represents 127 stays per year. The rate of alcohol related harm hospital stays is 731 per 100,000, worse than the average for England. This represents 2,012 stays per year.
- Levels of breastfeeding and smoking at time of delivery are worse than the England average.
- Smoking prevalence is 18.7%, which is similar to the England average. The rate of smoking related deaths is 324.3 per 100,000 aged 35+, worse than the average for England. This represents 1,791 deaths per year.

The complete health profile and updates can be found by following these links:
http://fingertips.phe.org.uk/profile/health-profiles/data
**St. Helens Health Profile Summary**

The health of the people in St. Helens (population 176,000) generally worse compared to the England average. Some headlines taken from the PHE health profiles and updates are:

- Deprivation and child poverty are higher than average, with 25.0% (8,075) children living in poverty.
- Life expectancy for men and women is lower than the England average. Life expectancy is 11.2 years lower for men and 9.9 years lower for women in the most deprived areas of St. Helens than in the least deprived areas.
- Estimated levels of adults with excess weight (67.5% overweight or obese) are similar to the England average. Levels of obesity (29.3%) are higher than the England average. In Year 6, 22.1% (385) of children are classified as obese, worse than the average for England.
- The rate of alcohol specific hospital stays among those under 18 is 99.5 per 100,000, worse than the average for England. This represents 109 stays per year. The rate of alcohol related harm hospital stays amongst adults is 855 per 100,000, worse than the average for England. This represents 1,486 stays per year.
- Levels breastfeeding and smoking at time of delivery are worse than the England average.
- Smoking prevalence is 19.7%, which is similar to the England average. The rate of smoking related deaths is 355.1 per 100,000 aged 35+, worse than the average for England. This represents 1,058 deaths per year.

The complete health profile and updates can be found by following these links:

http://fingertips.phe.org.uk/profile/health-profiles/data
6. Understanding local Dental Health needs across the life course

In general, there has been an improvement in adult’s dental health, although for older people dental needs can be very complex. The information examining dental access issues for adults is good. However, there is not enough information collected which examines the dental health of adults, particularly longitudinal data.

However, there is sufficient data to look at children’s dental health. Information is routinely collected and published on children’s dental health at ages 3, 5, 8, 12 and 15 years old. This means that there is more information on the dental health of children compared to adults.

Healthy teeth are important for children’s overall health. Tooth decay affects many children in the UK. Untreated tooth pain can cause pain and infections that may lead to problems with eating, speaking, playing and learning. The links between deprivation, smoking and excessive alcohol consumptions were discussed above on p.16. Breastfeeding is presumed to be a protective factor, but there is no evidence available.

There is some local data on nutrition available when lifestyle surveys are carried out. However, although the most recent Merseyside lifestyle survey included a section on nutrition, it does not cover sugar consumption, so is not directly relevant to dental health. There are no routinely collected local indicators on nutrition. Local annual health profile data from Public Health England does include levels of obesity, but recent systematic reviews have found mixed evidence for the association between obesity and poor dental health. The British Dental Association has recently produced a position paper on this topic, noting that obese children are not more likely to have dental decay of baby teeth. For adult teeth, there is a small overall association between obesity and

71 Merseyside health an

dental decay. Although further research is needed, local data on levels of obesity can be used as a proxy for poor nutrition associated with poor dental health.

**Child Dental Health**

**Headlines of the 2011/12 Children’s Dental Health Survey:**

- Significant improvements for 12 and 15 year olds observed in every national survey since records were first established in 1973 continue. However, the improvements noted for 5-year olds in previous surveys appear to have slowed down.
- 12 years of age is the key age at which dental health of children is internationally compared (as it is at the start of the permanent dentition being fully established). In England, in 2003, the mean number of those with teeth decayed, filled or missing teeth (DMFT) in 12 year olds was 0.7, the lowest since records were first established.
- 12-year-old children in England now have the best dental health of their age in Europe.
- The proportion of 12 and 15 year-olds having permanent teeth with obvious decay experience has decreased significantly between the 1993 and 2003 surveys. There was also a significant decrease in the proportion of 12 and 15 year-olds with filled permanent teeth.
- In 2003, 57% of 5-year-olds, 62% of 12-year-olds and 50% of 15-year-olds in the UK had never experienced any decay or needed dental restorations.
- In 2003 the proportion of 5-year-olds who had never known decay in England was 59%.
- The proportion of five and eight year-olds that received dental restorations has declined significantly since 1983. However, in both five and eight year-olds filled primary teeth represented a significantly smaller proportion of the total obvious decay experience than in previous surveys.

---

73 British Dental Association (2015)  
[http://www.bspd.co.uk/LinkClick.aspx?fileticket=17BxGRXFTbo%3D&tabid=147](http://www.bspd.co.uk/LinkClick.aspx?fileticket=17BxGRXFTbo%3D&tabid=147)
National Dental Epidemiological Data for 3 and 5 year olds

Data from the National Dental Epidemiological Programme for England, Oral Health Survey of 5 year old children, 2012 by local authority has recently been published and more information can be found by following this link: [http://www.nwph.net/dentalhealth/survey-results5.aspx?id=1](http://www.nwph.net/dentalhealth/survey-results5.aspx?id=1)

Nationally improvements in dental health amongst 5 year olds were observed in the 2012 survey. This has been partly attributed to the reduction in availability of low fluoride children’s toothpaste. Across Merseyside, over the last few years there has been considerable re-focussing of oral health programmes towards those based on the delivery of fluoride toothpaste (including postal schemes and supervised brushing programmes) - so it is likely that the 2012 results reflect the impact of these programmes.

A change from negative to positive consent for the 2007-8 and all subsequent surveys means that comparison with earlier survey data cannot be made.

Overall, across all Merseyside local authorities, the trend is a general reduction in prevalence of dental decay (Figure 2a). A further 5 year olds’ survey is currently being undertaken across Cheshire and Merseyside with the fieldwork due for completion in April 2015.

![Merseyside: % with decay experience at 5 years old 2007/8 compared to 2012](http://www.nwph.net/dentalhealth/survey-results5.aspx?id=1)

With the exception of Sefton, the proportion of 5 year olds with experience of dental decay was above the England average in both the 2008 and 2012 surveys. The 2012 surveys reported a
reduction in prevalence for all Merseyside local authorities – in Liverpool, St. Helens and Halton this reduction was statistically significant (Tables 2 and 3).

Table 2: Data for 5 year olds showing the average number of decayed, missing and filled teeth per child, at the Local Authority, North West and England level.

Key for tables 2 and 3:
- **Drawn sample**: total number of validated children appropriate to take part in the survey, selected in accordance with Pine et al. (1997b).74
- **Number examined and (%)**: total number of validated children actually examined, and the percentage of validated children from the drawn sample actually examined.
- **d₃mft**: average number of obviously decayed, missing and filled teeth per child
- **d₃t**: average number of decayed teeth per child
- **mt**: average number of missing teeth per child
- **ft**: average number of filled teeth per child
- **%d₃mft**: percentage of children with decay experience (i.e. with one or more obviously decayed, missing and filled teeth)

---

**Adult Dental Health**

Headlines of the 2009 national Adult Dental Health Survey show:

1. Across most of the indicators of oral health and disease there has been a continuous improvement in adult’s dental health.

2. For all indicators of oral health the continuation of improvement in younger age groups first detected over 20 years ago are now evident up to age 45 years.

3. For older people and older middle aged people, dental needs can be very complex and for those with gum disease or decay, disease can be extensive.

4. In general, good personal health behaviours are shown to be associated with better health and a greater proportion of dentate adults than ever before are engaging in these behaviours.
7. Dental Treatment

One way of exploring dental health is to examine the forms dentists use to record information about what treatment they have provided to patients, which gives a valuable insight into the type of treatment being provided in an area, oral health needs (whether there are higher levels of complex treatments indicating that there may be a higher need for services and/or illness prevention) and patient attendance behaviour (whether there are higher levels of urgent treatments which could relate to less general dental health). This data is available for both child and adult patients.

**The type of treatment being provided in Merseyside**

Dental treatment is organised into 4 separate charge bands which give an indication how complex the dental treatment is.

The NHS Dental Charges from 1st April 2014 are:

- Band 1 treatment; £18.50
- Band 2 treatment; £50.50
- Band 3 treatment; £219.00
- Urgent treatment; £18.50

Analysis of the numbers and proportions of charge bands can provide insight into the type of treatment being provided in an area, oral health and patient attendance behaviour. It is also one facet of analysing “access” data namely the ‘realised access’ (see Harris 2013 for a further discussion). A patient information leaflet which explains patient charges and other dental services can be found by following this link:

Figure 3 shows the percentage point difference by local authority area compared to national levels for adults as recorded on FP17s (see p.27 for explanation of FP17s). The national level has been labelled as the benchmark, so if the national level is 70% and a local authority has a proportion of 60 then the local authority will be shown as -10.

---

75 There are 3 standard charge bands for all NHS dental treatment, depending on the level and complexity of the treatment provided. Band 1: e.g. an examination, diagnosis, advice on health promotion, scale & polish, Band 2: e.g. all listed previously, plus fillings, root canal work or removal of teeth, Band 3: e.g. all listed previously plus crowns, dentures and bridges, finally, there is a band for ‘urgent care’.

76 Harris, R.V (2013) Operationalisation of the construct of access to dental care; a position paper and proposed conceptual definitions. Community Dental Health
Figure 3: Charge Band % point difference for Adults to England Level 2013/14

Source: NHSBSA Information Services, 12th June 2014

Figure 3 indicates a number of areas of interest:

1. Band 1 treatment is lower than the national average for all Merseyside local authorities, and very low (approximately 12% lower than the national figure) for Liverpool. This indicates that people in Merseyside attend less for routine dental care than it would be expected. Reasons could include:

   A. People in Merseyside have problems accessing dental services, although access for other types of treatment is greater than the national average so this is unlikely to be the case.

   B. People in Merseyside have better overall dental health than the national average and therefore need to attend the dentist less, although this is unlikely as treatment in more complex Bands (Band 2 and 3) is greater than the national average.

   C. Due to a reason which is unclear from this chart, people in Merseyside delay accessing dental care until they have a more serious dental health issue which falls into Band 2 or Band 3 treatment. We would need more information to explore this, but one explanation could be that this delay in treatment could be related to the charges of Band 1 treatment and how they are considered as non urgent and therefore non-essential costs thus people are more likely to put this type of treatment off.
2. Conversely, looking at the Band 3 treatment we can see that it is much higher than the national average for all local authorities in Merseyside, particularly for Knowsley and Liverpool. This indicates that people in Merseyside have a much greater uptake for complex dental work than would be expected, particularly in Knowsley and Liverpool. Reasons for this could include:

A. People in Merseyside have worse dental health than would be expected and therefore have more complex treatments as a result. This is likely as they access the dentist overall at similar or greater levels than the population nationally.

B. People in Merseyside have a greater access to Band 3 level treatments than the population nationally. Historically, people from lower socioeconomic groups were more likely to have their teeth extracted than people in higher socioeconomic groups, to prevent further costly dental work on poor quality teeth. This cohort is ageing and therefore, there will be more people who require crowns, dentures and bridges than would be expected nationally.

Finally, there is another important area of interest that the chart draws attention to.

3. The further the spread of the band charges (coloured dots) from the benchmark (purple line) of the national figure, the more unequal the dental health of the population in that local authority. For example, Knowsley has less than expected numbers of people attending for prevention care, with higher numbers of people than the average attending for complex care. This has implications which include:

A. People in lower socioeconomic areas are less likely to have good dental health, and there are a number of reasons for this (see section on deprivation, p.48 & 72). This chart indicates that people in the most deprived local authorities in Merseyside (Knowsley and Liverpool) have less chance of preventing poor dental health as they are attending dental practices less than they should for routine and health promotion reasons.

B. People in higher socioeconomic areas are more likely to have good dental health and there are a number of reasons for this. This chart indicates that people in the less deprived local authorities in Merseyside (Sefton, St. Helens and Halton) are more likely to have better dental health as they are attending dental practices more than the other areas, and near the national level.

Therefore, there is an indication that there could be inequalities in dental health as indicated by the type of treatment received.

There is also an indication that illness prevention and health promotion work should target people in Merseyside to increase the proportion of people who visit the dentist for routine and illness
prevention work. It is possible that this could decrease the numbers of people attending for more complex and therefore usually more costly work.

Figure 4 below shows the percentage of child FP17s by charge band for child patients resident in Merseyside. It shows that the Merseyside figures are similar to the figures for England. However, the number of children receiving Band 1 treatment is slightly less than the national average yet the number of children receiving Band 2 treatment is slightly more than the national average.

**Figure 4: % of Child FP17s by Charge Band 2013/14 for patients resident in Merseyside**

![Bar chart showing % of Child FP17s by Charge Band for patients resident in Merseyside.](image)

Source: NHSBSA Information Services, 12th June 2014

Figure 5 below show a breakdown of band information by age group, for all patients resident in Merseyside.

In general, the younger the child, the more often the treatment is basic or routine (Band 1). 95% of patients aged 0-2 years old receive the most routine dental care and this is the same for the rest of the country, on average.

In comparison, only 60% of children aged 13-17 receive routine dental care (Band 1), 30% of children aged 13-17 receive more complex care (Band 2) and around 2% of children aged 13-17 receive Band 3 treatment.
Figure 5: % of FP17s by Charge Band and Patient Age Range 2013/14 for patients resident in Merseyside

Source: NHSBSA Information Services, 12th June 2014
There are also differences in the ages a child receives urgent dental treatment. Only 3% of children aged 0-2 have had urgent dental treatment (both in England and Merseyside) yet almost 7% of children aged 6 to 12 and 13-17 in Merseyside have had urgent dental treatment, more than 1.5% above national levels.

Figure 6 below shows the percentage point difference by area compared to national levels.

- The number of Band 1 treatments in Knowsley and Liverpool is much less than the national average and the number of Band 2 treatments in Knowsley and Liverpool is much greater than the national average.
- The lower the incidence of Band 1 treatment, the greater the need for Band 2 treatment, as evidence suggests that delaying dental treatment can lead to more complex treatment in the future.
- Band 3 treatment is approximately the same across all areas of Merseyside and is similar to national levels.
- Urgent care is also similar across Halton, Knowsley, Sefton and St. Helens, but is higher in Liverpool than other areas, and on the whole is higher across Merseyside than England.

For further explanation of the dental services available, how to find an NHS dentist, what treatment you can get and how much it will cost from 1st April 2014, please see the link below;

Patients who are exempt from paying towards the costs of treatment

Patients are split into 3 types according to age and exemption status;

1. Paying Adults: - pay a charge to the full cost of treatment

2. Non Paying Adults: - exempt or remitted from paying a charge to the full cost of the treatment

3. Children

Table 4 below shows the numbers of adults in Merseyside who are exempt from paying towards dental care costs and the reasons why they are exempt.

Table 5 shows the number of children in Merseyside who are exempt from paying towards dental care costs and the reasons why they are exempt.

Re-attendance rates and what they can indicate

The interval between one course of dental treatment and the next is an important measure of the quality of service provided. National Institute of Clinical Excellence (NICE) guidelines recommend an interval of between three months and two years, depending on the oral health of the patient. Intervals shorter than three months fall outside the NICE guideline range, and may indicate poor quality treatment or diagnosis.

Even within the NICE guideline range, a large proportion of intervals at the lower end of the range may indicate unnecessary re-examinations of patients.

An area with a high proportion of FP17s falling within shorter periods could indicate:

- poor quality of treatment or diagnosis
- unnecessary re-examinations of patients
March 2015, Liverpool Public Health Observatory, Dental Health Needs Assessment, Merseyside

- poor dental standards
- a lack of understanding or implementation of the NICE Guidelines
- poor dental health in an area

The percentage of re-attendance for child patients on Merseyside between 6-12 months is more than 10% lower than the national average (Figure 7).

**Figure 7: % of FP17s by re-attendance interval for child patients resident in Merseyside**

![Graph showing re-attendance intervals for child patients in Merseyside compared to England.](image)

Source: NHSBSA Information Services, 12th June 2014

**The intensity of resource use by Units of Dental Activity information**

The average number of units of dental activity (UDA) claimed for each patient is a fundamental measure of the intensity of resource use. High rates can indicate a number of areas of concern:

- Resources are not being managed in the most cost effective way
- Patient access is being compromised
- Unusually high frequencies of treatments
- An unusual mix of band 3 treatments compared to other bands
- A genuinely high level of need in that area

The average UDA per patient is calculated by dividing the total number of UDA for children by the number of child patients treated. The number of patients treated is a count of the unique patient identities on scheduled FP17s based on contracts located in the area.
Figure 8 shows the average rate for contracts location in each local authority area, with an England and Merseyside rate shown as a benchmark.

![Figure 8: UDA per patient for child patients resident in Merseyside 2013/14](image)

Source: NHSBSA Information Services, 12th June 2014

**Extraction data for children in Merseyside**

For the majority of patients, dental treatment is provided with the use of local anaesthesia (LA) with or without the additional use of sedation, however for some patients the provision of dental care with LA with or without sedation is impossible. Department of Health Guidance published in 2000 stated that from 1st January 2002, all dental care provision under general anaesthesia (GA) should be provided in a hospital setting. The groups of patients who may require dental treatment under general anaesthesia are:

- Young children requiring extraction of decayed teeth (usually multiple teeth)
- Extremely anxious children requiring dental extractions and restorative care – who have been unable to accept treatment with LA even with the additional use of sedation

---

- Children with behavioural problems who may require pre-medication and for whom treatment with LA and sedation has been unsuccessful
- Children who require minor oral surgery procedures
- Adults with learning disabilities who are unable to accept dental care with LA and sedation

The largest group of patients requiring dental care under general anaesthetic are children requiring removal of multiple decayed teeth – this frequently follows at least one episode of acute pain or infection. Despite improvements in children’s dental health, there are still significant numbers of children in Merseyside who require this service.

The extraction data for children by local authority area is published by PHE and is available in more detail here:

http://www.nwph.net/dentalhealth/extractions.aspx

The database gives details about admission of children to hospital for extraction of one or more decayed primary or permanent teeth (Table 6). Information focuses on 0 to 19 year olds and is available for 2011/12 and 2012/13 by (former) PCT and local authority of child’s residence and grouped by Government Office Region. Data were extracted from the Hospital Episode Statistics (HES) dataset which records inpatient care from National Health Service (NHS) hospitals across England. Within this dataset, a unit of care (a finished consultant episode [FCE]) equates to the period a patient spends under the care of a single hospital consultant.

No assumptions can be made about the method of anaesthesia provided for these procedures but it is likely that the majority of episodes involved general anaesthetic. It is possible that different coding protocols are applied in some sites and this could explain some of the variation.

The vast majority of teeth extracted will have been removed because of decay, particularly in children aged 5 and 8 years old. In older children it is likely that an increase in the number of extractions will be for orthodontic purposes. In some instances the data are an underestimate of the number of admissions, as the Community Dental Service may provide the extraction service in hospital premises but the episodes may not be included in hospital data recording.

The ONS report describes the dental health of children at ages 5, 8, 12 and 15 years old.

Table 7 is taken from the British Dental Association and Royal Pharmaceutical Society Health Histories Series (2011). They have data which shows there is a decrease in the proportion of 8, 12 and 15 year olds over time that have had extractions, across all social classes in 2003. The proportion of extraction for social classes IV and V tends to lag behind that for social groups I, II, and III non-manual. The table below shows how the proportion of 15 year olds who have had an extraction in the lower SES groups in 1993 is similar to that of the higher SES groups in 1983, and again proportions are similar in 2003 for lower SES groups as they are in 1993 for higher SES groups.

ONS (2003) suggest that attempts to reduce the number of admissions to hospital for the extraction of teeth need to address several areas, which include: engagement of primary and secondary care providers; establishment of clear acceptance criteria and triage of referrals; provision of training and
support for primary care teams in the management of caries among children in acute and chronic stages; commissioning and implementation of oral health improvement interventions with the local authority; and clear agreement about provision of support for families before and after hospital admission in an effort to avoid repeat admissions in the future.

**Treatment provided, re-attendance intervals and deprivation**

This section provides an analysis of the courses of treatment (CoTs) by treatment band and IMD 2010 for child patients resident in the area. The analysis examines the treatment bands, Bands 1-3 and also treatment called ‘Urgent’. The total number of CoTs for residents in the area have been analysed by IMD National Quartiles, with percentages of the total for each treatment band and quartile used for comparative purposes.

Generally it is expected that Band 1 Treatments are the most frequent. However the proportion that is made up of Band 1 treatments may differ depending on deprivation. In the most deprived areas, Band 1 treatments often account for a noticeably lower proportion than the overall proportion, with higher levels in each of the other treatment bands. An inference from this is that in more deprived areas there are higher levels of more serious treatment, reflecting increased dental need. In the least deprived areas, treatments involving check-ups and examinations reflect lesser needs.

Re-attendance patterns are based on the length of time between re-attending at an NHS dentist for patients resident in the area. As previously mentioned, NICE guidelines recommend that the recall interval should be appropriate to the level of risk of dental disease for each patient. For adults the recommendations are that the shortest interval (exceptionally) should be 3 months. The longest should be 24 months, where there is no sign or risk of dental disease in the patient. If guidelines were being followed then a relatively small proportion of treatments would be expected to be within 3 months of a previous course of treatment.

**Figure 9** below shows the proportion of total FP17s by re-attendance intervals under a year for child patients resident in the area by the relative deprivation of the patients’ resident area, defined as before using IMD National Quartiles.

A high proportion of re-attendance interval within 3 months could signify greater dental need whilst low levels in the 6-12 month interval may suggest that a significant number of child patients are not having the regular check-ups.

**Figure 9** below shows;
- For Band 1 treatments, children are more likely to be in the least deprived group (74%) of the population than in the most deprived group (61%). The likelihood of having a Band 1 treatment increases with affluence. Overall, more children have Band 1 treatment than any other form of treatment.

- For Band 2 treatments, there are 10% more children needing Band 2 treatments in the most deprived group compared to the least deprived group. The number of Band 2 treatments is approximately half (27% versus 66%) as many as Band 1 treatments, overall.

- For Band 3 treatments, numbers are very small, but there would appear to be no difference between whether the child is in the most deprived group or the least deprived group in terms of accessing complex dental care.

- For urgent dental care, a child in Merseyside is twice as likely to need urgent care if they are in the most deprived group compared to the least deprived group.

**Figure 9: Treatment bands for child patients resident in Merseyside 2013/14 as % of total FP17’s by IMD national quartiles.**

Source: NHSBSA Information Services, 12th June 2014
Domiciliary FP17’s for adult patients

Domiciliary dental care is dental treatment that is provided in the patient’s home. It was outside the scope of this piece of work to focus on domiciliary or out of hours care for adult patients. However, data taken from the FP17 forms indicating dental treatment given, shows that in 2013-14, seven people were seen by domiciliary dental care services aged 44 and under. For the 45-74 age group, 31 people were seen. For the over 75 years old group 62 people were seen.

Collating postcodes of domiciliary service providers with other known indicators on expected levels of need and mapping service providers to the geographical boundaries of local authorities would be further useful work. It would be helpful to see if domiciliary services are providing a service which best meets the needs of the local population.
8. Dental Service Access and Availability

This chapter of the dental health need assessment in Cheshire and Merseyside explores a number of issues around access to and availability of dental services including looking at access and availability from a geographical perspective. We also present data in this chapter, exploring the differences in localities in Cheshire and Merseyside in the child and adult patient access rates, patient centred factors that may promote or hinder access, deprivation and its impact on access rates, and the opening times of practices in each local authority.

The concept of ‘access’ to services

Getting ‘access’ to dental care is often cited as one of the most important concerns that the population and therefore politicians have, regarding dentistry. In the 1990s in many areas of the country NHS dentists decided to move their practices into the private sector, thereby limiting the amount of NHS services available. Since dental practices can provide a mix of NHS and private care it is often difficult to measure the complete extent of provision of dental services to the population (data on private dental services are not available). The needs assessment does not include consideration of the contribution of the private sector to meeting the population’s dental needs.

However, for completeness the information we gathered during the telephone survey with every registered CQC dental practice in Merseyside is presented in chapter 6. Nevertheless, because the private sector contributes, sometimes significantly to the supply of dental services, and hinges on an individual’s ability to pay, the availability of NHS dental services is often an equity and therefore a public health issue.

‘Access’ to services is a term commonly used to mean the ‘ability to make use of services’, and so politicians and policy makers often use this to capture their concerns about the equity or fairness of people’s ability to use dental services which are local to them. This ‘service availability’ aspect may have different dimensions which make utilisation difficult such as:

- Proximity of the NHS practice (the pertinent issue may not just be the geographic distance but it’s ease of use bearing in mind public transport links)
- Dental practice opening times to accommodate work commitments/carer responsibilities etc.

‘Service availability’ issues may not just involve the currently available local NHS dental practice capacity in the area, but also the population’s knowledge about the availability of local services, how
to access these services, and any eligibility for exemption from NHS charges. Perceived availability of NHS services may be different from actual availability and may be just as much an equity issue as the availability of NHS dentistry itself.

‘Service availability’ however only captures one aspect of what it means to ‘access’ dentistry. It only captures issues about ‘opportunity to access services’ (Harris 2013)\(^{78}\)-although this dimension is the most easily measured and captures most readily the issues around (perceived or real) limited availability of NHS dental services.

There are however other aspects of dental service utilisation which are known to reflect inequalities in the population – and could also be considered as contributing to issues about ‘access to dental care’. This reflects current views that health-seeking behaviour is generally viewed as a series of steps and sequential ‘barriers’ to receiving effective and equitable care; and that inequalities can arise at a number of points in the process.

They are:

- Differences in readiness to seek care (low socio-economic groups) more often seeking care when in pain
- Candidacy – once a patient gets in contact with a service, how readily they are received for a course of treatment on an equitable basis to other patients seeking care
- Equitable, effective care – how likely a patient is to receive evidence-based care. For example, because of a stereotyping of patients, low SES patients may be less likely to receive certain types of care. This includes a whole set of measures including patient satisfaction measures as well as care outcomes as reported by patients (PROMs).

**Measures of ‘access’**

In this Dental Health Needs Assessment, when ‘access rates’ are referred to, the measure used is

- the proportion of the population who have attended a NHS dentist in the past 24 months

This is generally used merely to reflect the ‘service availability’ dimension of access to care. The data is readily available because it reflects political and policy driven concerns about limited ‘access’ to NHS dental services.

---

\(^{78}\) Harris, R.V (2013) Operationalisation of the construct of access to dental care; a position paper and proposed conceptual definitions. Community Dental Health.
March 2015, Liverpool Public Health Observatory, Dental Health Needs Assessment, Merseyside

It does not take into account:

- The number of times the person has attended the service within 24 months.
- The amount of care provided and whether this is effective or equitable care.
- The amount of care needed to make sure a person’s oral health is corrected.

Future needs assessments should move to start to address these wider issues to do with equity of access to NHS care.

Research studies have been focusing on dental health and the factors which improve or worsen oral and dental health for many years. There is now a body of research, which suggests that socioeconomic disadvantage impacts on oral health and that the more disadvantaged a person is, the more likely it is they will have poor oral health\(^79\). Research also suggests that lack of availability to dental care services also explains why some people do not seek dental treatment. Usually, it is reported that increasing levels of socioeconomic disadvantage is associated with worsened oral health but, simultaneously, with decreased utilisation of dental care services. People with severe socioeconomic disparities were 7–9 times as likely to refrain from seeking the required dental treatment. Studies report\(^80\) that these associations persist even after controlling for living alone, education, occupational status and lifestyle factors. Lifestyle factors explained only 29% of the socioeconomic differences in poor oral health among men and women, whereas lack of availability to dental care services explained about 60%.

This health need assessment will draw together the available evidence on availability of dental care services in the Merseyside area.

\(^80\) Wamala, S., Merlo, J., Bostrom, G (2006) [http://jech.bmj.com/content/60/12/1027.full.pdf+html](http://jech.bmj.com/content/60/12/1027.full.pdf+html)
LPHO telephone survey

During February 2015, the researchers in LPHO conducted a telephone survey with Care Quality Commission registered dental practices (both private and NHS) to determine the level of availability the local population had to dental appointments, the waiting times, and the provision of adult NHS services in Merseyside in February 2015.

Aim

The aim of this telephone survey was to gather information to inform the dental health needs assessment. We particularly wanted information on how accessible and available CQC registered practices are to the local population and sought information on;

1. The opening times of each practice including out of hours opening times
2. Usually, how long existing patients would wait for a routine dental appointment
3. Whether the practice was accepting new NHS adult patients (either currently, at that point in time or ever), and therefore, are they fully private practices.

We are aware of the limitation in survey data and also how this data only presents us with an approximation of the services available in Merseyside at that point in time. The survey was conducted during December 2015 (for opening times information) and weeks 1 and 2 of March 2015 (for NHS access and appointment waiting times).

Method

Dental practice lists were taken from the Care Quality Commission and researchers organised them into Cheshire and Merseyside based practices based on the coding in the CQC spreadsheet. A total of 192 Merseyside practices were contacted by the researchers, with 172 able to provide details for the survey. Those excluded were practices that were specialist hospital, community or prison based; the 4 orthodontist practices; and those listed practices that were duplicated - they had different telephone numbers and names listed although the practice was the same. The researchers phoned each practice until they were able to speak with us and provide information with regards to the opening times of the practice, including out of hours availability, i.e. at least one weekday beyond 9am-5pm and/or at least occasional Saturday opening. Waiting times for routine, non-emergency appointments and whether they accepted NHS patients, and whether they had an NHS contract were the main areas of questioning. The researchers entered all the information into a spreadsheet and details of this are available by request.
Results

This section describes the results of the telephone survey; whether there is the option to seek NHS dental care in Merseyside, whether practices provide out of hours care for patients and how long a usual wait time is for a routine appointment in an NHS practice.

NHS access

Merseyside had a total of 172 dental practices which provided information for this survey. As shown in Figure 11, 1 in 4 practices (25.0%) are fully private, not accepting any adult NHS patients. Only just over half of all practices registered on the CQC list had current spaces for NHS patients at the time of the survey (53.5%, 92 practices, early March 2015). Of NHS practices only, 71.3% were currently accepting new NHS adult patients.

There were 8 practices which although not currently accepting new NHS patients, said they will be able to do so in April 2015.

Compared to the rest of Merseyside, Liverpool had relatively fewer practices currently able to accept NHS patients (only 41.8%) and Halton had the most (68.8%). Almost 1 in 3 (31.3%) of practices in Liverpool were fully private, compared to only 13.6% in Knowsley.

NHS out of Hours access

Of the 128 dental practices in Merseyside that accept NHS patients, more than 1 in 3 (37.8%) had good out of hours provision on a weekday, opening before 8.30am and/or after 6pm at least one day per week (Figure 12). A further 36.2% had limited out of hours provision, between 8.30 and 6pm.
March 2015, Liverpool Public Health Observatory, Dental Health Needs Assessment, Merseyside

Just over 1 in 4 (26.0%) had no out of hours access, only opening Monday to Friday 9-5pm. Liverpool had the highest levels of good out of hours access (45.7%).

**Figure 12**

Out of Hours Weekday Service
% of NHS dentists open OOH weekdays, early March 2015

1 in 10 NHS dentists in Merseyside were open at least occasionally on a Saturday (10.1%), with 7% having regular Saturday sessions (Figure 13). St. Helens had the highest proportion opening on a Saturday, at 15.8% (10.5% opened regularly).

**Figure 13**

Out of Hours Saturday Service
% of NHS dentists open Saturdays, early March 2015

NHS appointment waiting times

Practices were asked how long an NHS patient would usually have to wait for a routine dental appointment. Across Merseyside, almost three-quarters of practices (74.2%) reported that patients would usually be seen within 2 weeks (Figure 14).
There was some variation between local authorities - St. Helens had the highest proportion of practices being able to offer routine appointments within two weeks at 78.9%, and Halton had the least, at 66.7%.

Figure 14

### Strengths and Limitations of this survey

**Strengths**

- A survey is a useful way of collecting data from a large number of respondents and also provides a high level of capability in representing the large population of dental practices.
- From the 192 practices listed in Merseyside, we contacted and retrieved information from 172 appropriate practices (excluding orthodontists, prison based practices and duplicates).
- Numerous questions could be asked relatively cheaply and quickly and analysed quickly which suited the nature of this task.

**Limitations**

- It is possible but unlikely, due to the nature of the questions that the respondents, usually dental practice receptionists, may not provide accurate answers to the questions, and this could be for a number of reasons.
- The respondents may be uncomfortable providing information which presents them in an unfavourable light e.g. how long does a patient usually wait for a routine appointment.

**Conclusions**

Before we conducted the telephone survey we had produced GIS maps to locate the CQC list of dental practices and map them in accordance with the index of multiple deprivation, noted which practices were near care homes to see if services were appropriately located for the older
population, and plotted drive and walk times to see whether the population could reasonably access the locations of the dental practices. However, once this survey data was collected we revised the maps to only include the dental practices that provide NHS adult care.

In discussion with the steering group, the authors of the report feel that the provision of NHS dental practices accepting new NHS patients is good in Merseyside.

**Proximity to local dental practices**

This section explores how close to local populations dental practice are using walking and drive time maps. Dental access by deprivation quintiles is also considered. This enables assessment of any differences in accessibility to primary care dental services for different local authorities. These local authority-specific maps can be found in each of the local authority summaries provided at the front of the report.

For driving, an 8.4 minute drive was used assuming the national speed limit minus 10%. For walking access was assessed using 15 and 30 minute availability, assuming an average walking speed of 2mph. Where areas outside of a local authority are accessible within the times above, the shading has been shown on the map. Accessibility is limited to the road network within the local authorities shown.

The maps included below relate to the Merseyside geographical region. The individual local authority maps in the summaries at the front of the report show accessibility to dental practices within the chosen authority. For example in the drive maps, the blue shaded areas show where residents can access a dentist within 8.4 minutes in their local authority. White areas are those where they cannot access a dentist within that time. They may be able to access a dentist within another Cheshire and Merseyside authority in 8.4 minutes, but this is not shown on the individual maps in the summaries. In addition, these maps have some blue shading that is not within the local authority, these are Cheshire and Merseyside residents who could drive into a local authority and access a dentist within 8.4 minutes. The overall Merseyside map (Map 2, p.61) shows accessibility to any dentist within Merseyside. Any white areas on this map are areas of inaccessibility, i.e. where they cannot access a Merseyside dentist within 8.4 a minute drive.

**Walk Time Maps:**

Map 1 provides an overview of the level of access to dental practices across Merseyside if the person requiring access is only able to walk to the nearest practice. The orange areas are within 15 minutes
walk of a dental practice and the yellow area are within 30 minutes walk of a dental practice. There are areas of Merseyside that are outside the areas deemed a ‘reasonable distance’ from a dental practice. This indicates there is a need for more dental practices to be located away from current dental practices to serve populations of Merseyside who are currently unable to walk a reasonable distance to a dental practice.

Drive Time Maps:
Map 2 shows how nearly every part of the Merseyside area is within a reasonable distance by car, to access a dental practice and these are the areas shaded blue.
Map 1: Dental practice accessibility across the Merseyside area; practices within walking distance
Map 2: Dental practice accessibility across the Merseyside area; practices within a reasonable driving distance
Indices of Multiple Deprivation (IMD) Maps:

The IMD 2010, part of the English Indices of Deprivation, is an overall measure of multiple deprivation experienced by people living in an area\textsuperscript{81}. It is a composite score based on 38 indicators grouped in seven domains: income; employment; health and disability; education, skills and training; barriers to housing and other services; crime; living environment. Each domain’s contribution to the overall score is weighted differently, with income and employment deprivation weighted the most.

IMD 2010 scores are published for small geographical areas known as ‘Lower Super Output Areas’ (LSOAs).

- The local authority average deprivation score is a ‘population weighted average’ of the combined scores for the LSOAs in a local authority.
- The local authority extent most deprived measure is the percentage of people in the local authority living in the most deprived fifth (‘quintile’) of LSOAs in England.

Maps exploring IMD levels and geographical locations of dental practices have been produced to identify:

- Whether more dental practices are located in areas of high deprivation as there is evidence to suggest there would be more dental care need in these areas.
- Whether more dental practices are located in areas of low deprivation where need may be lower.
- Whether there are enough dental practices in areas with high levels of need.

Map 3 shows:

- Dental practices are not evenly spread geographically across Merseyside
- Areas of high deprivation seem to have more dental practices than areas with low deprivation at the Merseyside area level
- Affluent areas of Merseyside can be directly next to areas of deprivation and there is not always a gradient of IMD Quintiles, across Merseyside in a geographical nature.
- Dental practices are concentrated around places of high deprivation and therefore areas where you could expect high levels of need such as Liverpool city centre, Halton, north Liverpool the north Sefton area and parts of Knowsley, and areas which serve both deprived and affluent communities such as Waterloo and St. Helens. There is also a concentration of dental practices in areas of affluence such as Formby, Rainford, Childwall and Mossley Hill.

Map 3: Merseyside IMD 2010 Quintiles showing geographical location of dental practice and level of deprivation by geographical location.
Can the population of Merseyside obtain dental services when they need to?

An important aspect of the effectiveness of dental commissioning is the ability of patients to obtain needed dental treatment when they request it. One measure used to describe this access is the number of patients seen as a proportion of the resident population; the ‘access’ rate. Access rates can be affected by the amount of dental provision in an area, the oral health needs of the population, the deprivation or the prosperity of the resident populations and many other factors. A low access rate does not equate solely to a lack of provision. Access rates are expressed as a percentage of the area population and are calculated using 24 months of scheduled data.

Figure 15 below shows the child access rate for each local authority area in Merseyside in order to highlight any changes over time and enable comparisons between different localities within the overall area. Figure 15 shows that the rate of children attending the dentist is gradually decreasing in Halton. In Knowsley, Liverpool and Sefton the rate is more stable and in St. Helens the rate of children accessing the dentist is increasing slightly.

Figure 15: Child Access Rates Trend by Local Authority in Merseyside (2011-14)

Figure 16 below shows the adult access rate for each local authority area in Merseyside in order to highlight any changes over time and enable comparisons between different localities within the overall area.
The figure shows that:

- In every local authority except for Halton, the adult access rate is increasing.
- The biggest difference in access rates in Merseyside is between Liverpool who have the lowest access rate (for all years) and Sefton who have the highest access rate (for all years).

Figure 17 shows the access rate for children, by age group, for each local authority in Merseyside. For all age groups under 18 years old, except in Liverpool for the 13-17 year olds, the rate of accessing dental services is higher on average than the national rate. By the time a child is starting school the majority of children (72.3% across Merseyside) will have accessed dental services in the previous 24 months and by 12 years old 88% (across Merseyside) of children have accessed dental services within the previous 12 months.
Figure 17: Merseyside Local Authorities Child Access by Age Bands March 2014

Figure 18 below shows the differences in Merseyside (by local authority and by age band) in the percentage of the population who access dental health services compared to the England average.

For younger adults in each Merseyside local authority, access is greater than the national average for all ages except for the 18 to 24 age group in Liverpool. In Liverpool the low proportion of the population who access dental care aged 18-24 may be a reflection of the young student and professional population. The ONS census (2011)\(^2\) for Liverpool reports that there are 61,484 people aged 19-24 years old, which is 13.2% of the population of Liverpool. Young people who live in Liverpool as part of the student population (of Liverpool Hope University, Liverpool John Moore’s University or University of Liverpool) are required to register with a GP surgery but are not required to register with a dental practice. Therefore, many students will continue to access the dental services near their home town, except for emergency care. Overall, 26.8% of the population of Liverpool aged 18-24.

\(^2\) [https://liverpool.gov.uk/media/128963/Population.pdf](https://liverpool.gov.uk/media/128963/Population.pdf)
Liverpool are aged 15-29 years old compared to 19.9% nationally and this could explain the low level of dental access for this age group.

Figure 18: Merseyside Local Authority Adult Access by Age bands (March 2014)
For middle aged to older people (45-75+) the access rate across the local authorities is:

- Halton: Higher than the national average except for the 75 years and over population
- Knowsley: Higher than the national average except for the over 75s.
- Liverpool: Lower than the national average for the 18-24, 65-74 and 75+ age groups and near the national average for the other groups.
- Sefton: Higher than the national average access rate for all groups.
- St. Helens: Higher than the national average rate for all groups, with 75+ age group being close to the national average.

Figure 19 below shows the access rate for each local authority area in Merseyside in the most recent period (March 2014) compared with Merseyside and England. The figure shows that;

- For all local authorities except Liverpool, the adult access rate is better than the national average.
- The difference between the rate of adults accessing dental health services in Liverpool is 14% behind the rate for adults accessing dental services in Sefton.
- The percentage of the adult population accessing dental services is very similar for Halton, Knowsley and St. Helens.

**Figure 19: Adult Access (March 2014) by Local Authority in Merseyside compared with Merseyside and England Average**

Source: NHSBSA Information Services, 12th June 2014
Map 4 shows the child access rate per ward in the Merseyside area. The wards coloured in red have the lowest rates of access and the wards shaded in blue have the highest rates of access. The highest child access rate (where a high number of children access the dentist over a 24 month period) is in wards of South Liverpool and wards of South Sefton. The lowest child access rate is in wards in Central Liverpool, Halton and North Sefton. The differences in access are not unexpected as research evidence shows that the most deprived areas often have lower access rates and the most affluent areas often have higher access rates. Deprivation and dental access is discussed in more detail on pages 48 and 72.

Map 4: Access rate Resident Child Patients in Merseyside 24 month period until March 2014
Patient centred factors that promote or hinder access to services

Previous research shows that some of the obstacles to attending the dentist were linked to patient centred factors such as dental anxiety, the costs of treatment or the attributes of the dental practice. In the national Adult Dental Health Survey (2009) there is a chapter focusing on ‘access and barriers to care’ http://www.hscic.gov.uk/catalogue/PUB01086/adul-dent-heal-surv-summ-them-the8-2009-re10.pdf

Nationally, treatment costs, dental anxiety, and the dentist/patient relationship appear to be related to health and care outcomes. Being previously affected by treatment costs was associated with delaying attendance and having a poor level of oral health. The influence of cost on decisions about dental treatment applied to some degree to all groups in society.

Dental anxiety is recognised as a key barrier to dental care and the ADHS (2009) report confirms the expected relationship between dental anxiety and visiting the dentist. It also indicates its association with dental health. The inter-relationship of the barriers considered in the ADHS report has not been assessed and research is scarce but it seems likely that these barriers interact in complex ways.

A summary of the national findings is presented below. Local data is not available.

The cost of dental treatment

The ADHS (2009) reports that nationally, 26% of people said that the type of dental treatment they had opted for had been affected by the cost and 19% said they had delayed dental treatment due to cost. The figures for the North West population are similar to the national figures.

- Differences in the proportion of adults who said that cost had an effect on the type of dental treatment were observed between age groups. Over 30% of adults aged 25-34, 35 to 44, 45 to 54 were influenced by cost compared to 15% of those aged 74-85 and 11% of over 85s.
- Overall, 20% of women were influenced by cost and 17% of men.
- There was a higher proportion (20%) of more deprived people who delayed dental treatment because of cost, compared to those in a higher social group (17%) and these national figures are similar to the North West figures.

---

83 Finch et al (1988) Barriers to the receipt of dental care, Social and Community Planning Research
Dental anxiety and the relationship to oral health

Dental anxiety ranges from people who feel relaxed during dental treatment to those who are dentally anxious but who cope, to those people who are dentally phobic and avoid dental care.\(^{84,85}\)

In the ADHS (2009) the MDAS\(^{86}\) scale was used to assess the level of dental anxiety. From a total of 25, a score above 19 indicates extreme dental anxiety, indicative of dental phobia.

Nationally:

- 51% of people scored 5-9 indicating no/low levels of anxiety
- 36% of people scored 10-18 indicating a moderate level of anxiety
- 12% of people scored 19+ indicating extreme levels of anxiety
- 30% of people would be very anxious if they were getting tooth drilled
- 28% of people would be very anxious if they were having a local anaesthetic injection

Dental anxiety peaks age 16-24 when 15% of this group score 19+ on the MDAS, which then gradually decreases with age until age 85+ when there is a peak in anxiety levels (with 9% of people scoring 19+ on the MDAS).

The relationship between levels of dental anxiety and self-assessed dental health is complex. Poorer dental health may stem from neglect arising from the avoidance of dental care due to anxiety about visiting the dentist or it may be that some individuals expect that they need considerable dental treatment and are therefore extremely dentally anxious. For example, 10% of adults with good or very good self-assessed dental health were very/extremely anxious about going to the dentist compared with 34% of adults with bad or very bad self-assessed dental health. Overall, 9% of those who rated their dental health as good or very good had an MDAS score of 19 or more compared with 30% of adults with bad or very bad self-assessed dental health.

Relationship with the dentist and dental practice

A number of questions\(^{87}\) were asked in the ADHS (2009) to try to establish the factors which may influence people attending the dentist and subsequently inform policy in improving dental services.

---

\(^{85}\) Swallow JN. (1970) *Fear and the dentist.* New Society: 5; 819-821

\(^{86}\) Humphris, Morrison, and Lindsay (1995) The Modified Dental Anxiety Scale: validation and United Kingdom norms. *Community Dent Health* Sep 12 (3) 143-50
• Nationally, there were no differences between men and women and the quality of the relationship with their dentist.

• Younger people tended to be more negative about at least one element of their most recent interaction with the dentist (22% of 16-24 and 26% of 25-34) compared to older people (16% of 65-74 and 17% of 75-84).

• People who self reported that their dental health was bad or very bad were more negative across all questions than people who self reported that their dental health was good or very good. For example, for question 1 “Did the dentist listen carefully to what you said about your oral health?” 26% of people with bad or very bad dental health were negative, compared to 6% of people with good or very good self reported dental health.

• There was a socioeconomic gradient in reporting negative elements in the most recent interaction with a dentist, so 7% of people in the highest SES group said the dentist had not listened carefully to them compared to 11% of people in the lowest SES group. Previous research suggests that improving communication between health professionals and patients is key to increasing satisfaction with services88.

• A large majority (80%) of those interviewed were satisfied with all aspects of their interaction with the dentist at their most recent visit but this was not universal. The quality of the relationship between dentist and patient assessed at the last visit to a dentist was markedly associated with the patients’ assessment of their overall self-rated dental health, the length of time since their last dental visit and their level of dental anxiety. Generally speaking people whose last experience with a dentist was problematic gave a low rating of their own oral health, had not attended for a longer time and were more likely to be extremely dentally anxious than those whose experience was more positive. These findings suggest that dentist-patient communication, whilst generally good, can be a real barrier to achieving optimal dental health and care in just the same way as other more familiar barriers such as cost and anxiety.

---

87 These questions asked the respondent to indicate whether: 1) the dentist had listened carefully to what they had to say about their oral health; 2) they had been given enough time to discuss their oral health; 3) they were involved in the decisions about any dental care or treatment they may have needed; 4) they got answers that they could understand from the dentist; 5) the dentist treated them with dignity and respect; and 6) they had confidence and trust in the dentist. The purpose of these questions was to determine the success of the interactions between patients and dentists and to investigate whether people felt involved in decisions about their oral health.

Where is the dental service need the greatest in Merseyside?
Research has shown\(^{89,90}\) that dental disease correlates closely with social and economic deprivation, meaning that usually, dental need is greater in areas of deprivation and in areas of prosperity, dental need is less. There has been a reported seven fold difference between the populations of (former) PCTs in England with the best dental health compared to the worst dental health\(^{91}\). The British Dental Association Oral Health Inequalities Policy (2009) has set out their commitment to reducing health inequalities through addressing the factors that can influence poor oral health such as diet and nutrition, oral hygiene, fluoride exposure, tobacco, alcohol and injury and have also set out their commitment to promoting initiatives and actions that tackle health inequalities in oral health across the population.

Socio-economic factors that are key determinants of oral health inequalities include deprivation, age, gender, ethnicity environment, psycho-social factors, poverty and lifestyle. Some of these factors are outside the scope of this report, but more information on the British Dental Association’s report (2009) can be found here: http://www.bda.org/Images/oral_health_inequalities_policy.pdf

Measuring Deprivation
The Index of Multiple Deprivation (IMD)\(^{92}\) 2010 is the official measure of relative deprivation for small areas in England. It combines a number of indicators, chosen to cover a range of social, economic and housing issues into a deprivation score for each small area in England. These small areas are called Lower Layer Super Output Areas (LSOAs) and have an average population of 1500 people (also see p.62).

The aim of linking the IMD levels to the LSOAs is to assess whether the area population is noticeably over-represented in the most deprived areas and under-represented within the least deprived communities compared with England as a whole.

The data used in the following figures and tables, was the 2011 population estimates for LSOAs in England and Wales by Single Year of Age and Sex, ONS. Amalgamated rates may differ. The number

\(^{89}\) The Office of National Statistics (1998), Adult Dental Health Survey, Oral health in the United Kingdom

\(^{91}\) British Association for the Study of Community Dentistry, 2003/04 survey of five-year-olds

\(^{92}\) More information on calculating IMD levels can be found here:
of patients is based on the home postcode recorded in the personal details of each FP17, and if this information is not available then the patient was not included in the data presented.

Table 8 shows the percentage of the Merseyside region population (approximately 1,507,000 people) who are ranked into the deprivation quartiles compared to the percentage of the population of England.

Table 8 below shows that over 50% of Merseyside are considered to be in the ‘most deprived’ group (56% children/ 52% adults) compared to 28% of children and 24% of adults in England. 9% of children and adults in the Merseyside population are considered to be in the ‘least deprived’ group compared to 25% of England.

It also shows the proportion of Merseyside’s child and adult population attending an NHS dentist that falls within each IMD 2010 quartile. The aim is to assess whether access is noticeably affected by levels of deprivation. Table 8 shows that in all groups, access rates are higher than the national average for child and adult access to dentists.

The table highlights a number of interesting areas which show that children’s access to dental services is good in the Merseyside area:

- 56% of the Merseyside population of children are in the most deprived quarter of the population nationally and 70% of this group access dental services. This is slightly higher than the national average of nearly 68%.

- Only 56% of the most deprived group of adults access dental services, therefore, around half the most deprived group do not access dental services.
Around 9% of the Merseyside population is in the most affluent quarter of the population nationally and of these 9%, nearly 80% of children and 65% of adults access dental services. Therefore, a large majority of the most affluent children and adults in Merseyside access dental health services.

**Distance travelled and treatment locations**

The distance travelled to a dental practice can be seen as an indicator of need and effectiveness of dental commissioning. Distance travelled is calculated by measuring a straight line between the home postcode of a patient and contract location. Maps 1 and 2 above show how accessible dental practices are in Merseyside in terms of a reasonable walking and driving time (p.60 & 61).

We attempted to produce maps based on public transport accessibility but have been unable to do so.

**Opening times for practices**

Dental practices are not required to open between any specific times although in most areas there are some dental practices which open outside the usual working hours of Monday- Friday 9am-6pm. The opening times of practices have an impact on how often the general population can access dental services. As reported earlier in this section (p.53), the telephone survey found that the majority of NHS dental practices in Merseyside are open during ‘normal working hours’ of 9am-5pm. Many of the practices are open less than 9 hours per day. Some practices open for extended hours, for example, they may open 8am-4pm or 8am-7pm one weekday. The majority of the practices which open on a Saturday are only open in the morning (see Table 9 for numbers. Percentages are reported earlier in Figures 12 and 13).

**Reported success in obtaining a NHS dental appointment and overall experience**

The GP Patient Survey (2014) published aggregated 2012-13 (wave 2) and 2013-14 (wave 1) dental statistics. More information can be found by following this link: [http://www.england.nhs.uk/statistics/2013/12/12/2345gppsw1201314/](http://www.england.nhs.uk/statistics/2013/12/12/2345gppsw1201314/)

Patients were surveyed for their overall experience of primary care services, which includes dentists, and specifically asked questions about access\(^93\). 1.3 million adults were contacted and 450,000 replies received, with an overall response rate of 34%. National figures suggest that of the people who had tried to get a dental appointment in the previous 2 years;

- 84% rated trying to get an appointment a positive experience\(^94\)
- 93% were successful in getting an appointment
- younger adults and those from BME groups were less successful in getting an appointment.

From April 2010 it has been mandatory to complete the ethnicity marker on the FP17 so that commissioners can see if all ethnicity categories are being seen by dentists and therefore commission appropriate services to meet the needs of these groups.

In England, 75.9% of FP17s have attempted to record ethnicity including the times a patient has declined attending the dentist, compared to the Merseyside rate of 77.7%.

In England, 61.5% of FP17s have recorded the ethnic group of the patient, excluding patients who have declined attending the dentist, compared to a Merseyside rate of 66.7%.

Figure 20 below is taken from the GP Patient Survey 2014 results. It shows that nationally, in all ethnic groups, people were more successful in getting appointments in 2013 compared to the same period in 2012.

---

\(^{93}\) Questions in the GP patient survey included: 1. When did you last try and get an NHS dental appointment for yourself? 2. Was the NHS dental appointment you were trying to get with a dental practice you had been to before for NHS dental care? 3. What is your overall experience of NHS dental services?

\(^{94}\) ‘Positive experience’ is the result of 48% of people rating the experience very good and 36% of people rating the experience as fairly good.
Figure 20: The percentage of those who tried to get an NHS appointment in the last two years, who succeeded, by Ethnicity.

The GP Patient Survey (2014) also provides data at the level of Merseyside, Cheshire, Wirral and Warrington. Table 10 shows the proportion of people who were successful in getting NHS dental appointments. For Cheshire, Wirral and Warrington the response rate was 37%\(^{95}\), for Merseyside the response rate was 30%\(^{96}\) and for England the response rate was 34%\(^{97}\). The proportion of people able to successfully get an NHS dental appointment in Merseyside is above the national average (94% compared to 93% nationally).

Table 10: showing the proportion of people who were successful in getting NHS dental appointment and their overall experience of NHS dental services

\(^{95}\) 27,101 forms distributed, 9,911 forms completed  
\(^{96}\) 43,734 forms distributed and 12,943 forms completed  
\(^{97}\) 1,313,496 forms distributed and 447,133 forms completed
The overall experience of NHS dental services in the two NHS Area Teams of Cheshire, Wirral, and Warrington and Merseyside is also above the national average and overall positive experience of dental services is improving throughout England (particularly over the past 5 years). This could be for a number of reasons:

- There is an increase of the quality of service people receive. Evidence suggests\(^98\) that there is an increase in perception of improvement across the NHS Health and Social Care system, including dental health services. N.B. There is also a discussion about whether these perceptions are based on actual experience, media influence or political drivers, (see the BSA 29 report\(^99\) for further discussion).

- Increased funding, targets set for (the former) PCTs to improve access (following the Steele report\(^100\), 2009), a growth in the number of dentists carrying out NHS work and a new contract introduced in 2006, could have made a difference to the satisfaction of the public for dental health services, although as Figure 2 from the Kings Fund report shows (on the next page), the impact of these improvements were not seen until 2009 onwards.

- People may rate their overall experience of dental services as better in Cheshire and Merseyside than the rest of England as they are expressing their satisfaction with overall NHS services as a proxy for their satisfaction with dental health services.

- Alternatively, evidence has suggested\(^101\) that lower SES is associated with less health consciousness (thinking about things to do to keep healthy) and stronger beliefs in the influence of chance on health. Over half of the population of Merseyside is within the lower SES groups. Attitudes to health and health care can arise through variations in life opportunities, exposure to material hardship and ill health over the person’s life. Therefore, people from lower SES groups are more likely to be satisfied with health services in general, and to rate experiences as more positive than higher SES groups who are more likely to look critically at the interaction with health professionals, and the outcome of consultation.

Figure 21 below was taken from the Kings Fund (2011) report on the BSA survey results. The figure compares the satisfaction with dental services against GP services and reports that while satisfaction with GPs is decreasing, satisfaction with dentistry services is increasing. This indicates that people are not using the overall experience with NHS services as a proxy for their satisfaction with dental

care services. More information can be found here: http://www.kingsfund.org.uk/projects/bsa-survey-results-2011/satisfaction-nhs-services-results-1

9. Vulnerable groups and their dental experience

Aneurin Bevan launched the NHS on 5th July 1948 with one of the key principles being that it ‘meets the needs of everyone’.

One of the founding principles of the NHS is to provide a comprehensive service to all, “irrespective of gender, race, disability, age, sexual orientation, religion, belief, gender reassignment, pregnancy and maternity or marital or civil partnership status... at the same time it has a wider social duty to promote equality through the service it provides and to pay particular attention to groups or sections of society where improvements in health and life expectancy are not keeping pace with the rest of the population”\(^{102}\). In the context of the dental health need of and services provided to the populations of Cheshire and Merseyside, this principle is a reminder that dental need is likely to be greater in areas of psychosocial and material deprivation and that services should do all they can to maximise the improvements for groups who are vulnerable for whatever reason. For the purpose of this dental health need assessment we have been able to look more closely at the needs of some vulnerable groups in our local community; these include black and minority ethnic groups, children and adults with learning disabilities, homeless people, older people and the prison population.

Woods et al (2005)\(^{103}\) published “Vulnerable groups and access to healthcare; a critical interpretative review”. This was a report for the National Co-ordinating Centre for NHS Service Delivery and Organisation Research and Development with the aim being to produce a logical, plausible and useful explanation, grounded in a comprehensive but not exhaustive body of evidence about access to health care. They reported that people in more deprived circumstances do show a readiness to access health care services, but are more likely to manage health as a series of minor and major crises, rather than treating diseases as requiring maintenance and prevention. This is likely to be linked to the normalisation of ill-health in more deprived communities as well as the range of resources people are required to mobilise in order to use services.

Recently, the Royal College of General Practitioners (2013) provided guidance on improving access for extremely vulnerable groups including gypsies and travellers, homeless people and sex workers which was a guide to commissioners in CCGs and Health and Wellbeing Boards. More information can be found here: [http://www.nhsconfed.org/resources/2014/01/rcgp-guidance-on-improving-access-for-extremely-vulnerable-groups](http://www.nhsconfed.org/resources/2014/01/rcgp-guidance-on-improving-access-for-extremely-vulnerable-groups)

\(^{103}\) [http://www.nets.nihr.ac.uk/__data/assets/pdf_file/0004/81292/ES-08-1210-025.pdf](http://www.nets.nihr.ac.uk/__data/assets/pdf_file/0004/81292/ES-08-1210-025.pdf)
BME Groups

The NHS constitution, which applies to NHS dental services, states that a comprehensive service is available to all irrespective of race and that people have a right not to be discriminated against in the provision of NHS services on the grounds of race (NHS Constitution 2013)\textsuperscript{104}. However, differences in access to services do exist.

Inequalities in oral and dental diseases and access to dental services exist and evidence suggests that people living in deprived areas experience more tooth decay, periodontal disease and oral cancer than those living in more affluent areas. There is also variation in some oral diseases between different ethnic groups which is, in the main, related to social inequalities. There is some evidence from surveys to suggest differences in the way certain black and minority ethnic groups utilise dental services compared to the general population.

This section of the dental health needs assessment briefly covers the main areas of concern reported in the literature.

- Dental disease experience
- Uptake of dental services
- Barriers to access
- Cost
- Language
- Mistrust of dentists
- Culture and religious influence
- Differences in reasons for attendance

One study qualitatively interviewed 51 people most likely to experience deprivation in Kensington, Chelsea and Westminster in 2009\textsuperscript{105}. They found that the majority of the sample frequently visited the dentist (63.3% compared to 49% nationally) and that the group were less likely than the general population to have Band 3 treatment. However, interestingly, there was a significantly higher rate of extractions than in the general population (30.8% compared with 7.9%) and over 40% of the sample were not happy with previous treatment compared to 20% nationally.

There is limited research focused on access for black and minority ethnic groups to dental services in Merseyside and Cheshire, and most local evidence is small scale and descriptive. Figure 22 in the

\textsuperscript{104} https://www.gov.uk/government/publications/the-nhs-constitution-for-england

\textsuperscript{105} http://www.rbkc.gov.uk/pdf/dentistry%202009-10.pdf
previous section above presents national data indicating that those from minority ethnic groups are less successful at obtaining appointments.

**Children and Adults with Learning Disabilities**

**Background**

People with learning disabilities and autism are one of the most vulnerable groups in society, experiencing health inequalities, social exclusion and stigmatisation. Generally, children and adults with a learning disability often have greater and more complex needs than the general population and this is no different when accessing dental health services. They are also more likely than the general population to have needs that are not identified or treated\(^{106}\).

For the purposes of this dental health need assessment, the definition of a learning disability is\(^{107}\):

- significantly reduced ability to understand new or complex information, to learn new skills
- reduced ability to cope independently which starts before adulthood with lasting effects on development.

Learning disabilities are usually detected from childhood and can result from a number of causes such as genetics, chromosomal abnormalities or environmental factors. Sometimes there is no known cause for learning disabilities.

In 2013, Liverpool Public Health Observatory was commissioned to conduct a health need assessment for Merseyside and North Cheshire for children and adults with learning disabilities. The full report is available here:

[http://www.liv.ac.uk/media/livacuk/instituteofpsychology/publichealthobservatory/94,HNA,for,learning,disabilities,FULL,REPORT.pdf](http://www.liv.ac.uk/media/livacuk/instituteofpsychology/publichealthobservatory/94,HNA,for,learning,disabilities,FULL,REPORT.pdf)

For the health needs assessment, data was taken from the Learning Disability Observatory ‘Improving Health and Lives’ website and the ‘Projecting Adult Needs and Service Information system’ to estimate the expected numbers of people with learning disability and autism. Data on

---

people who are known to services, where available was taken from the NHS Information Centre (numbers reported by social services) GP QOF data and directly from local authorities.

Dental health

Evidence of poor dental health amongst those with learning disabilities was presented in a review of the literature by Ouellette-Kuntz in 2005\(^{108}\). There is an increased incidence of gum disease with gingivitis being 1.2–1.9 times higher than in the general population. Periodontal disease, oral mucosal pathology, and moderate to severe malocclusion occurred at rates seven times higher in the population with learning disability compared to the general population. Ouellette-Kuntz also noted a survey of health problems among adults with learning disability, which found that dental disease was the most common health problem present in 86% of the subjects.

The review also found evidence that knowledge and practice of dental hygiene is often poor among individuals with learning disabilities. The need for improved dental services for persons with intellectual disabilities was highlighted, with one study finding that 25% of individuals with learning disabilities had unmet dental needs and another that they were more likely to be admitted to hospital for dental procedures than the general population. A Lincolnshire health needs assessment found that hospital admissions for those with learning disability are more likely to be for emergency and for digestive symptoms (including dental caries) and injury and poisoning than in the general population\(^{109}\). A study by Emerson et al found that lower rates of routine dental care amongst people with learning disabilities have been reported\(^{110}\).

There is a shortage of literature on the dental health of people with learning disabilities who live in institutions. The Winterbourne View Serious Case Review provides evidence of poor quality care in Winterbourne View hospital, with some people reported as having poor dental health care\(^{111}\).

The Liverpool Public Health Observatory learning disability health needs assessment (see previous page) estimated that in Merseyside and North Cheshire, there are 33,579 people with a learning disability aged 18 and over, with only 5,325 who are known to services (2011/12). The health needs assessment included data on hospital admissions amongst people with a learning disability in Merseyside and North Cheshire in 2012/13. Dental caries (tooth decay) accounted for 7% of total admissions and 16% of elective admissions. They were the main cause of an admission and the main cause of an elective admission among the learning disability population in Merseyside and North Cheshire.

Box 1 gives an example of good practice in London relating to dental health and learning disability. The Department of Health’s ‘Valuing People’s oral health – a good practice guide for improving the oral health of disabled children and adult’s’ carries forward many of the key principles included in ‘Valuing people’, the Government’s White Paper on learning disability. The guidance recommends that oral health needs to be integrated into holistic health policy at all levels and should be included

<table>
<thead>
<tr>
<th>Box 1</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dental health and learning disability example of good practice: Westminster oral health project</strong></td>
</tr>
</tbody>
</table>

‘The Good Oral Health Project’ was commissioned by NHS Westminster and run in partnership with Westminster Learning Disability (WLDP) and the Central London Community Healthcare Community Dental Service (CDS). The aim of the project was to develop a better dental service in the Westminster area for adults with Learning Disabilities.

There were two phases to the project. The first phase was a baseline assessment of dental preventive, clinical, educational and service needs among the client group. The second phase involved a proactive approach to bring the most appropriate educational, preventive and treatment services to the clients.

- Of 411 people on the learning disability register: 318 were contacted, and 269 have been seen. Only 30 had their own ‘high street’ dentist
- Findings: 28% had dental decay, 11% had no teeth
- All service users seen were offered an oral health action plan.

As a result of this project the number of people receiving treatment within the Community Dental Service has almost doubled. Oral health awareness is much higher now in carers and support workers. The secret of their success was described as access to good data, a commitment from mainstream primary care services and commissioning and good partnership working between services.

_Taken from the ‘Improving Health and Lives’ website_  

---

112 Department of Health (2007) Valuing People’s oral health – a good practice guide for improving the oral health of disabled children and adults  
_http://www.sepho.org.uk/Download/Public/12757/1/valuing_peoples_oral_health%5B1%5D.pdf_
in every individual care plan. It has been noted that effective integration of oral health into the
mainstream health agenda is required to ensure oral health issues are not omitted or dealt with
separately and seen as 'the dentist's' problem\textsuperscript{113}.

**Homeless People**

People who are homeless find it more difficult to access primary care, preventive health services and
continuing treatment regimes. As problems are left to become more serious, they are more likely to
attend A&E or become hospital inpatients, using hospital services at a rate four to eight times
greater than the general population\textsuperscript{114}.

The range of health problems faced by single homeless people have been widely documented\textsuperscript{115}. They are likely to have complex health needs, including inter-related mental health problems, drug misuse problems, and alcohol dependence. Single homeless people are also at increased risk of injury, pneumonia, tuberculosis, dental problems and hypothermia\textsuperscript{116}.

A Northern Irish oral health needs assessment in 2007\textsuperscript{117} found that homeless people had greater experience of tooth decay compared with adults in the general population. They had greater numbers of missing and decayed teeth, lower numbers of filled teeth and higher levels of gum disease. Increased experience of discomfort, toothache and difficulty with eating due to decayed teeth were also found amongst homeless people. The effect of being older and homeless for longer was reflected in the increased experience of missing teeth and gum disease.

The homeless population was significantly more dentally anxious than the general population, with 27% of the sample having test scores that were indicative of dental phobia, compared with 10% in the general population.

Nearly 50% of the sample stated that they felt at least 'occasionally' ashamed and/or felt selfconscious about the appearance of their teeth. This would suggest that for these homeless people, quality of life was affected by their oral health status and in particular the appearance of their teeth.

\textsuperscript{113} British Dental Journal news section: http://www.nature.com/bdj/journal/v204/n2/full/bdj.2008.24.html
\textsuperscript{114} Homeless Link (online) Health and Homelessness. http://homeless.org.uk/health#.UtUY8ftta_g
A Scottish study in 2011 found that depression in Scottish homeless people is related to dental health status and oral-health-related factors\(^\text{118}\). The authors concluded that improving dental health care and oral-health-promoting activities for this group would not only benefit the primary outcome, namely, oral health, but also have the potential to indirectly reduce the low self-esteem, hopelessness and depression acutely felt in people experiencing homelessness.

Liverpool Public Health Observatory recently undertook a health needs assessment of homelessness in Liverpool City Region\(^\text{119}\). This included a summary of the national and local Homeless Link audit findings. The national Homeless Link audit found that 8 in 10 (82%) single homeless people have one or more physical health conditions\(^\text{120}\). The top four reported physical health needs related to joints/muscular pain; chest pain/breathing; dental; and eyesight. Dental problems were reported by 29% of single homeless people. The audit was replicated in Liverpool, where almost one third (32%) reported dental problems\(^\text{121}\). (Liverpool was the only Liverpool City Region local authority to have undertaken the Homeless Link audit).

In the Liverpool homelessness audit, although 1 in 3 homeless clients had dental problems, access to dental care for homeless people in Liverpool was not as good as access to GPs, with 39% not registered at all. However, since 2006 when the new dental contract came into place, there has been no need to register with a dental practice. An individual can call for an appointment or have an emergency slot at any practice if they have availability. Liverpool have linked Brownlow Group GP practice with Ropewalks dental practice to ensure that any homeless population who need dental treatment can have one place that they can attend which is central to the city centre.

**The Faculty for Homeless and Inclusion Health, Charter of Healthcare Standards**

The Faculty for Homeless and Inclusion Health has published a Charter of Healthcare Standards for healthcare professionals, which they should expect to meet when coming into contact with individuals who are homeless\(^\text{122}\). This included a standard for dental care, which stated that the

---

commissioners for healthcare for excluded groups must identify an individual to champion access to
dental care (e.g. head of dental services) (p.34 of Charter).
The Northern Irish oral health needs assessment\textsuperscript{123} mentioned on the previous page concluded that
dental fears and anxieties about the appearance of their teeth are real concerns for this client group
and must be incorporated into planning initiatives. In addition, their chaotic lifestyle means that a
combination of treatment opportunities (such as mobile clinics with other health professionals in
hostel localities) must be provided in conjunction with consultation and essential assistance from
healthcare co-ordinators for homeless populations.

**Older People**

As the population ages and the numbers of older people increase, the complexity of their dental
health needs will also increase; there will be an associated rise in demand on the service and a
change in the nature of care required. Older people’s dental treatment can be complicated and
preventing oral disease and maintaining dental health will contribute to keeping treatment simple
and help older people to stay healthy in the general sense.

Successive national Adult Dental Health Surveys have shown each cohort retaining more teeth than
their predecessors. Research evidence\textsuperscript{124} often reports that for older people, oral or dental health is
not seen as important as it should be, particularly to older people who may be frail and unwell.
Worden (2006) surveyed 126 care homes in the north west of England to see which assessment
tools were used to determine residents’ health and noted that oral health was only infrequently
mentioned.

Research studies report that residents in care homes have more unmet needs than older people
living in the community, fewer teeth than their peers in the community and more poorly fitting
dentures\textsuperscript{125}.

There is a growing evidence base of the challenges faced by older people in accessing dental health
services. Use of professional dental services is low amongst older people, particularly the
socioeconomically disadvantaged\textsuperscript{126}. Challenges include:

- Impaired mobility in frail elderly people hinders access to care
- Older people living in rural areas may find poor public transport systems difficult to navigate

\textsuperscript{124} Worden (2006) [http://www.tandfonline.com/doi/pdf/10.1080/13607860600637794](http://www.tandfonline.com/doi/pdf/10.1080/13607860600637794)

\textsuperscript{125} Steele (1998) [http://www.nature.com/bdj/journal/v189/n11/full/4800840a.html](http://www.nature.com/bdj/journal/v189/n11/full/4800840a.html)

There can be a financial hardship following retirement and the cost of dental work can be a worry

A lack of dental tradition amongst older people can present a barrier to accessing services

Older people may have negative attitudes towards oral health care

Another challenge identified as specific to older people was whether the locations of dental practices and care homes made it logistically possible to reasonably expect residents of care homes to be able to access dental services.

The World Health Organisation has published guidance called “Active Ageing”\textsuperscript{127} in which it emphasizes how important oral health promotion is for older people in terms of the impact of oral diseases on general health and quality of life. The World Health Organisation Oral Health Programme encourages national oral health planners to strengthen the implementation of systematic oral health policies to improve quality of life for older people\textsuperscript{128}.

A National Improvement Strategy was published by the Scottish Government in May 2012 focusing on priority groups including frail older people, people with special care needs and homeless people\textsuperscript{129}.

**Dependent older people**

With the aim of evaluating existing oral health practices, staff training and the impact of poor oral health, Public Health England (PHE) carried out a North West Survey of dependant older people\textsuperscript{130}. This was conducted as part of the dental public health intelligence programme in England and covered services supporting dependant elderly people in three settings:

1. ‘Care in your home’ (CIYH) services provided by agencies, for care of adults over 65 years.
These services may be provided by local authorities or in private contract with the client or their family. PHE note that a far greater number of older people receive support from CIYHs than live in residential care, and it is therefore possible that the impact of such services on oral health could be substantial both in the short and long term.

\textsuperscript{129} http://www.shancocks ltd.co.uk/download.php?op=view_article&article_id=356
2. *Adult residential and nursing homes, including hospices, in which adults over 65 years were resident.*

Older people in residential care are likely to be among the most dependent older people and have the highest needs for support with daily oral health care and assistance with identification of a need to seek treatment services. PHE point out that if oral hygiene or chronic or acute oral conditions are neglected then the impact can be great in terms of discomfort, exacerbation of pre-existing conditions, and ability to eat.

3. *Wards in hospitals providing in-patient care for adults over 65 years.*

It was noted that during a hospital stay, oral care may be of low priority when more challenging conditions are being treated, but if this is neglected in the long-term, the impact can be large with respect to infection and complications of other general conditions, discomfort and the ability to eat.

Of the ‘care in your home’ services, over a third (37%) did not undertake any formal assessment of clients’ oral healthcare needs. More than half (54%) provided no staff training on assessing a client’s need for assistance with oral hygiene (Table 10).

In contrast, a formal assessment of oral health needs was conducted in 90% of the residential homes in the survey (77% as part of a care plan). However there were still around two-thirds (32%) where there was no training provided for staff on assessing a client’s need for assistance with oral hygiene (Table 10).

In 84% of hospitals, a formal assessment of the oral health needs of patients aged over 65 on admission was carried out (53% as part of a care plan). More than 1 in 4 (28%) hospitals provided no training for staff in assessing patients’ needs for assistance with oral hygiene.

March 2015, Liverpool Public Health Observatory, Dental Health Needs Assessment, Merseyside

The surveys identified gaps in policy, training and knowledge across all agencies, but especially in ‘care in your home’ services. There was a clear demand for training by professionals and provision of leaflets and guidance. In residential homes there was a request for better access to domiciliary dental treatment.

Full results of all 3 surveys are available online at http://www.nwph.net/dentalhealth/oldersurvey.aspx

Using care home postcode data and dental practice postcode data we have mapped the geographical locations of care homes and dental practices to see whether the current provision is meeting the required need (Map 5). These maps also include the Index of Multiple Deprivation 2010 Quintiles to show where the locations of dental practices and care homes are, in terms of being in the most deprived or least deprived areas of the locality. As previously mentioned, we have also identified the NHS dental practices from the private dental practices.

- There is a concentration of care homes and NHS and private dental practices near cities and towns such as Warrington city centre, Birkenhead, Chester, Macclesfield, Wilmslow and Crewe.
- There are also areas of Cheshire with care homes which are not within reasonable distance to an NHS or private dental practice for example those to the south of Cheshire East

To access the care home maps for each individual local authority in Cheshire, please go to the Local Authority Summaries of the Dental Health Need Assessment at the front of the report.
Map 5: Dental practice accessibility and care home locations across Merseyside with IMD levels identified.
The Prison Population

‘The amount of untreated dental disease amongst all prisoners is approximately four times greater than the level found in the general population coming from similar social backgrounds.’

– Strategy for Modernising Dental Services for Prisoners in England 2003

The Ministry of Justice, National Offender Management Service North West Strategic Commissioning Plan for 2010-2013 published the numbers of prisoners in North West prisons and the percentage of the North West prison population in each prison. The national population of prisoners is 84,542 and the North West population is 11,068. Table 11 shows the numbers in each prison in the Cheshire and Merseyside region. More information on the most recent commissioning plan can be found here: http://www.justice.gov.uk/downloads/publications/noms/2010/north-west-regional-commissioning-plan.pdf

Providing dental services in a prison presents dentists with many unique challenges including;

- Concerns about threats to personal security
- Inability to move freely
- Delivering modern dental services in an environment which often require modernisation
- Compliance of prison specific clinical guidance

The challenges are illustrated in Figure 24:
Many prisoners suffer from mental health issues or learning difficulties, at higher levels than the general population\textsuperscript{132}. Dental issues may be exacerbated by complicated drug and alcohol addiction and dependence problems. The World Health Organisation\textsuperscript{133} (2007) reported that “prisoners with substance misuse problems are likely to report toothache very soon after entering prison, as any opiate drugs they took suppressed the toothache”.

It has been recognised that the prison population is generally from marginalised communities that have poor access to primary healthcare\textsuperscript{134}. The combination of this with an increasingly ageing population (people over 60 are now the fastest growing age group in the prison system\textsuperscript{135}), brings additional challenges to an already stretched prison healthcare system.

\textsuperscript{132} Department of Health (2003) Strategy for Modernising Dental Services for Prisoners in England
\textsuperscript{135} National Association of Prison Dentistry UK (2010) dentistry in prisons: a guide to working within the prison environment” Stephen Hancocks Ltd, London.
In 2008 a research study explored the oral health status of male prisoners in the UK\textsuperscript{136}. A total of 122 prisoners (mean age 36.4 yrs, with 43% of the sample being of white origin and 37% of black origin) were interviewed and then had an oral examination. A large proportion of the men reported tobacco use (80%), alcohol use (83%), drug dependency (84%) and having a high sugar diet (57%). Overall, oral health was poor. There were higher levels of decay than the general population and lower levels of missing and filled teeth. They also found a higher level of dental anxiety and a higher frequency of use of emergency dental services. Similarly, a study of prisoners in the north west of England showed that decayed, missing or filled teeth scores of people entering prison are around twice as high as those of the general population\textsuperscript{137}.

A report funded by the Department of Health was published in 2005 called “Reforming prison dental services in England. A guide to good practice” and outlines the challenges and some solutions to dental care access in prisons. More information can be found here: http://www.ohrn.nhs.uk/conferences/past/D160905PCW.pdf

It was previously suggested that one weekly clinical session for every 200 people in prison is an acceptable level of care\textsuperscript{138}; however, it is unlikely this will still be relevant because of the increase in the prison population. The transient nature of the prison population as a result of short sentences or being relocated to other facilities also means courses of treatment are often disrupted or left incomplete\textsuperscript{139}.

Access to dental care services for those in prison was reported in a 2014 Public Health England survey\textsuperscript{140}. The average waiting time for an examination was found to be less than six weeks in 55% of cases, with 35% having a wait of six to 12 weeks. Only 3% of dentists reported a waiting time for examinations of longer than 18 weeks. For treatment, over a third of patients (38%) are seen within four weeks, with 44% of people in prison waiting longer than four weeks and 12% waiting in excess of ten weeks

People in category B and C prisons were likely to wait six to twelve weeks for an examination, but three to four weeks for a follow up treatment appointment. People in category A and D prisons were

\textsuperscript{139} National Association for Prison Dentistry United Kingdom (NAPDUK) (2013) ‘The status of prison dentistry in England and Wales’.

more likely have an examination appointment within six weeks, and the follow-up treatment wait was five to six weeks.

The British Dental Association (2012) published a report which focused on the oral health needs of prisoners, and also proposed solutions to some of the issues presented above. Please see link for more information. [http://www.bda.org/Images/oral_health_in_prisons_eng.pdf](http://www.bda.org/Images/oral_health_in_prisons_eng.pdf)

A recent oral health needs assessment of vulnerable groups in London gives more details on the particular oral health problems and barriers to care that are faced by older adults, adults with learning disabilities, adults with serious mental illness, adults with drugs and alcohol abuse and homeless people[141]. Examples of interventions and resources available for improving the oral health of these groups of people are outlined. Recommended actions included:

- ensure all strategies and health plans for each vulnerable group have an oral health input
- develop oral health risk assessments and oral health care plans for each vulnerable group
- train dental staff in how to meet the particular needs of each vulnerable group
- improve access to services.
