# Wireless Communication Challenges

## Myths

- 1 communication bandwidth is unlimited**  
wrong! a limited range of frequencies, a limited amount of modulation possibilities
- 2 the number of channels = the number of frequencies**  
wrong! trade-off between width of the frequency channel and capacity,
- 3 low energy usage**  
wrong! wireless telecommunication is using huge amount of energy
- 4 unlimited reachability**  
wrong! many problems due to signal propagation peculiarities, irregular signal attenuation, multipath propagation, ...

## Energy

- 1 communication range depends on  $P_0$  – the signal strength at the sender,  
 $P_\Delta \approx P_0^{-d \cdot \Delta}$ , while  $P_\Delta$  should be above the noise level
- 2 strong signal  $\Rightarrow$  interference between different communication links

## Solutions

- 1 use minimal energy level  $\Rightarrow$  less interference, less electromagnetic smog!
- 2 divide the network into small cells

## Challenges due to mobility

- 1 unpredictable who belongs to the network
- 2 unpredictable communication needs
- 3 dynamically changing network state
- 4 physical problems  
(e.g. limitations on frequencies used for communication with moving stations)

Radio

# Access to the Radio Channel

# Problem

Radio  
Channel  
Access

M.Kutyłowski

challenges

radio access

solutions

bad guys

## Shared communication channel

- many stations may need to transmit at the same time
- if two stations transmit at the same time then a collision occurs – transmission failed

## Problem

how to organize leader election so that:

- the ratio between the transmission time and the global time is as close to 1 as possible
- i.e. minimize the time where:
  - channel silent
  - collision
  - messages devoted solely to leader election

# Network dynamics

Radio  
Channel  
Access

M.Kutyłowski

challenges

radio access

solutions

bad guys

## Highly dynamic networks

during the data transmission of the leader the other requests change

⇒ it does not make sense to find all nodes aiming to transmit

## Static networks

the requests change slowly

⇒ collect the requests once and then transmit one by one

# Technical conditions

Radio  
Channel  
Access

M. Kutylowski

challenges

radio access

solutions

bad guys

## Carrier detection

- 1 transmission of a single bits takes many periods of the carrier wave
- 2 carrier detection much faster than receiving any encoded message

## Synchronization

- 1 delays to receive the signal non-negligible
- 2 no full synchronization possible

## Time slots

- 1 execution time divided into time slots
- 2 necessary guard times between slots to compensate for (limited) asynchrony

# Carrier Sensing Multiple Access

Radio  
Channel  
Access

M.Kutyłowski

challenges

radio access

solutions

bad guys

## Steps of the protocol

Executed in a loop:

**if** there is a carrier signal, then stay idle time  $\sigma$   
**else** start own transmission

## Idea

somebody will be the first to try after the transmission end

# Carrier Sensing Multiple Access

Radio  
Channel  
Access

M. Kutylowski

challenges

radio access

solutions

bad guys

## Steps of the protocol

in time interval  $[0, T]$ . Steps executed by a station:

- 1 choose  $\eta < T$  at random
- 2 at time  $\eta$  sense the carrier
  - if there is a carrier signal, then stay idle
  - else send the carrier signal for the time  $[\eta, T]$ .

## Idea

the station that has chosen the smallest  $\eta$  is the winner

# Problems

Radio  
Channel  
Access

M.Kutyłowski

challenges

radio access

solutions

bad guys

## Delays

- 1 time between detecting the clear channel and starting to send the carrier signal
- 2 time between start of sending the carrier signal and receiving the signal by other station

## Consequences

- 1 station *A* detects clear channel at time  $t_0$
- 2 station *B* detects clear channel at time  $t_1 = t_0 + \epsilon$
- 3 station *A* starts sending the carrier signal at time  $t_0 + \lambda$   
( $\lambda > \epsilon$ )
- 4 station *A* starts sending the carrier signal at time  $t_1 + \lambda$

Both *A* and *B* think they are the winners.

# Error probability

## Condition

- $\eta_1, \dots, \eta_n$  time chosen by the stations  $A_1, \dots, A_n$
- $\eta_{1:n}, \dots, \eta_{n:n}$  - the same numbers after sorting
- error free if

$$\eta_{2:n} - \eta_{1:n} > \lambda$$

## Probability

Let  $T = 1$ . If time moments are chosen according to the distribution  $f$  with a cumulative density function  $F$ , then

$$\Pr[\eta_{2:n} - \eta_{1:n} > \lambda] = n \int_0^{1-\lambda} f(x)(1 - F(x + \lambda))^{n-1} dx$$

# Design choices

Radio  
Channel  
Access

M. Kutyłowski

challenges

radio access

solutions

bad guys

Uniform distribution ( $f = 1$ ),  $T$  arbitrary

$$\Pr(X_{2:n} - X_{1:n} > \lambda) = (1 - \lambda/T)^n .$$

Extending  $T$ :

- reduces error probability,
- increases transmission delay.

Unknowns

we do not know  $n$ , it could be anything between 0 and some reasonable upper bound

# Design choices

Radio  
Channel  
Access

M. Kutyłowski

challenges

radio access

solutions

bad guys

Is the uniform distribution the right choice?

**no!**

- 1 better probabilities for  $F(x) = x^\alpha$
- 2 even better for

$$F(x) = (e^{\alpha x^\beta} - 1)(e^\alpha - 1)$$

Optimum not known.

Practical issues:

there are limitations on  $F$ :

find the optimal  $F$  under the condition that choosing according to distribution  $F$  is very easy (small code, small computation time)

# Variants

Radio  
Channel  
Access

M.Kutyłowski

challenges

radio access

solutions

bad guys

## Large number of stations

A station willing to compete for the access to the radio channel:

- with probability  $p$  attempts to get the access
- with probability  $1 - p$  waits back-off time  $\sigma$  and restarts the procedure

All problems due to the static value of  $p$ .

# Continuous or discrete?

Radio  
Channel  
Access

M. Kutylowski

challenges

radio access

solutions

bad guys

## What is better?

- 1 choose probing points at random from continuous time distribution
- 2 or divide the time into slots and then block the slots?

Option 1 would be clearly better for delay  $\lambda = 0$ . But  $\lambda \gg 0$ .

# Slotted algorithms

## Two slots

two independent slots where a station can compete for the channel:

- $T = 3\lambda + 2\delta$
- slot 1: carrier sent at time 0, transmission of length  $\lambda + \delta$
- slot 2: is no carrier at time  $[0, \lambda]$ , start transmission at time  $\lambda$ , transmission of length  $\lambda + \delta$ ,
- at time  $2\lambda + \delta$  starting ACK of length  $\delta$

slot 1 chosen with pbb  $p$ , slot 2 chosen with pbb  $q$

# Two slotted details

Radio  
Channel  
Access

M. Kutylowski

challenges

radio access

solutions

bad guys

The probability of the success in one trial depends on parameters  $N$  (number of stations),  $p$  and  $q$ :

$$\Pr[\text{Success}] = Np(1 - p)^{N-1} + Nq(1 - (p + q))^{N-1} .$$

For  $p = \frac{a}{N}$  and  $q = \frac{b}{N}$ ,

$$\Pr[\text{Success}] \approx f_2(a, b) ,$$

where

$$f_2(a, b) = ae^{-a} + be^{-(a+b)} .$$

$f_2$  has a global maximum at point  $(a, b) = (1 - \frac{1}{e}, 1)$  and

$$f_2(1 - \frac{1}{e}, 1) = e^{-1 + \frac{1}{e}} \approx 0.531464 .$$

# Three slots

Radio  
Channel  
Access

M. Kutylowski

challenges

radio access

solutions

bad guys

1  $T = 4\lambda + 2\delta$

2  $p, q, r$  denote pbb of, respectively, starting to transmit at moment 0,  $\lambda$ , and  $2\lambda$ .

The probability of the success depends on parameters  $N$ ,  $p$ ,  $q$  and  $r$ .

$$\Pr[\text{Success}] = Np(1-p)^{N-1} + Nq(1-(p+q))^{N-1} + Nr(1-(p+q+r))^{N-1} .$$

For  $p = \frac{a}{N}$ ,  $q = \frac{b}{N}$  and  $r = \frac{c}{N}$ :

$$\Pr[\text{Success}] \approx f_3(a, b, c) ,$$

where  $f_3(a, b, c) = ae^{-a} + be^{-(a+b)} + ce^{-(a+b+c)}$

The function  $f_3$  has a maximum at the point

$$(a_0, b_0, c_0) = (1 - e^{-1+\frac{1}{e}}, 1 - \frac{1}{e}, 1)$$

and

$$f_3(a_0, b_0, c_0) = e^{-1+e^{-1+\frac{1}{e}}} \approx 0.625918 .$$

# General case - $k$ slots

for  $i \leq k$ :  $p_i$  is the probability of

- choosing by a station the transmission time  $(i - 1)\lambda$
- sending at this moment a message of length  $(k - i) \cdot \lambda + \delta$  (if the channel was clear so far)

# General case - $k$ slots

Pbb of a successful transmission by a single station:

$$\Pr[\text{Success}_{p_1, \dots, p_k}] = \sum_{i=1}^k N p_i (1 - (p_1 + \dots + p_i))^{N-1}$$

Let  $p_i = a_i/N$  and

$$f_k(a_1, \dots, a_k) = \sum_{i=1}^k a_i e^{-(a_1 + \dots + a_i)} .$$

Then

$$\Pr[\text{Success}_{a_1/N, \dots, a_k/N}] \sim f_k(a_1, \dots, a_k) .$$

### Optimization

Let  $(M_k)_{k \geq 1}$  be the sequence of reals defined by the following recurrence relation:

$$\begin{cases} M_1 & = & \frac{1}{e} \\ M_{k+1} & = & e^{-1+M_k} \end{cases} \quad \text{for } k \geq 1 \quad (1)$$

### Theorem

The maximum value of the function  $f_k$  is  $M_k$  and the maximum occurs at the point  $(b_k, \dots, b_1)$  where

- $b_1 = 1$
- $b_a = 1 - M_{a-1}$  for  $a = 2, \dots, k$ .

## Optimization for $N$ versus a running protocol

- 1 we do not know the number of competitors
- 2 the competitor stations may appear with a certain pbb distribution

how do the protocols behave in this case?

## Full Buffer

each of  $N$  stations has always something to send

## Poisson

requests to send appear with the Poisson distribution

# Some simulations results

Radio  
Channel  
Access

M.Kutyłowski

challenges

radio access

solutions

bad guys

## Situation

$A$  and  $B$  are the same station, it pretends two stations to increase chances

## Test

testing whether  $A$  and  $B$  are really different:

- 1  $A$  send some  $k$  messages,
- 2 other stations create collisions so that some of the messages are jammed
- 3  $B$  has to answer which has not been jammed

## Idea

if  $A$  is sending, then (for some devices)  $A$  cannot monitor the channel for collision. So if  $A$  and  $B$  are in reality the same device, then  $B$  does not know the answer.
