

Fusion

Stars are not just nature's way of lighting up the universe...

they are the "fusion factories" that make the elements heavier than hydrogen.

BUT...

Where does the hydrogen come from in the first place?

That's a very good question, but the answer is too long to be given here. Perhaps the solution is a future talk on the "The Beginning of Everything"?

ABC Stellar Evolution / Fusion

5

Star Formation

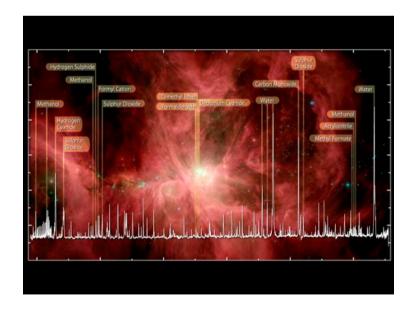

Where do stars come from?

Anyone can make a star in 7 easy-to-follow steps...

- 1. Start with a big cloud of hydrogen
- 2. Wait...
- 3. Wait some more...
- 4. Wait a bit longer...
- 5. Wait another 100,000 years...
- 6. Wait a bit longer...
- 7. You now have a star

ABC Stellar Evolution / Birth

What Triggers Star Formation?

Giant Molecular Clouds float around the galaxy

- They look like clouds
- They consist mainly of hydrogen molecules
- They are big (~100 light years across)

What makes a GMC collapse? Triggers may include...

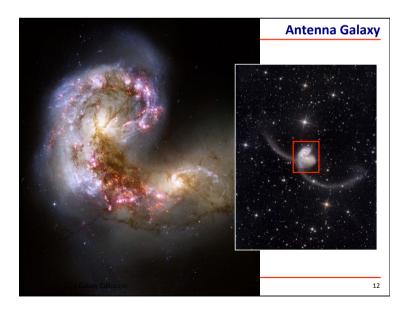

- One cloud colliding with another
- Shock waves rippling through the cloud
- Galaxy collisions (!)

ABC Stellar Evolution / Birth / Collapsing Cloud

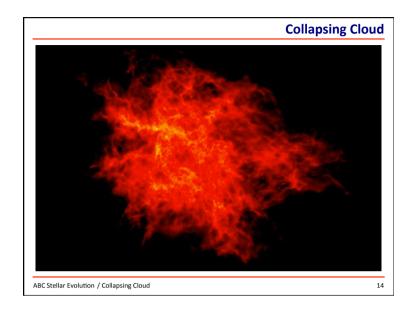

a

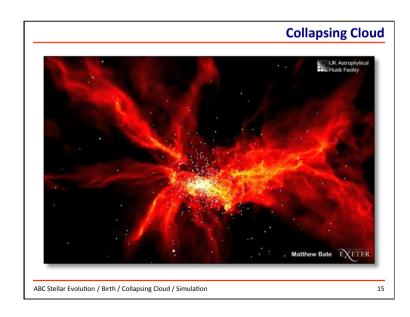

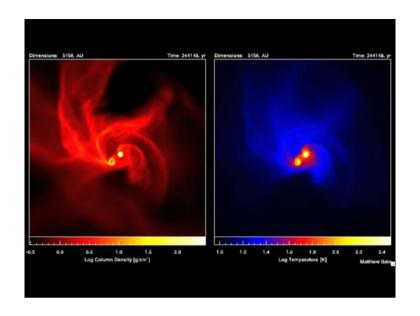

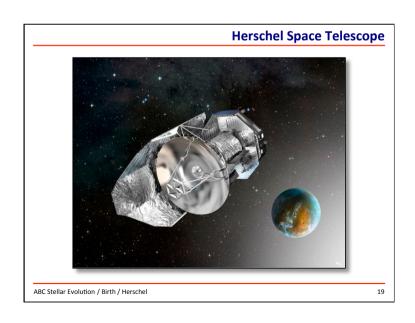

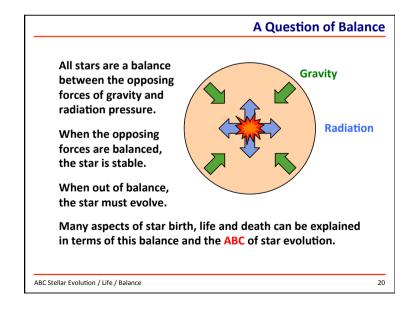

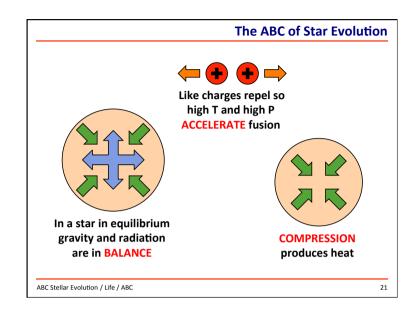

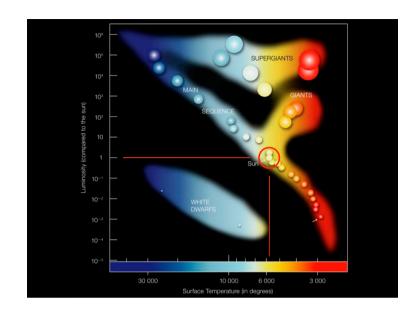

Live Fast, Die Young

Stars of different mass follow quite different lives.

High Mass stars have a lot of fuel, but...

- Gravitational forces are very strong
- Balance requires a lot of radiation to be generated
- Nuclear fuel must be used at a prodigious rate

Rather than living for billions of years, like our Sun, high mass stars may live for only a few million years.

ABC Stellar Evolution / Life / Mass

23

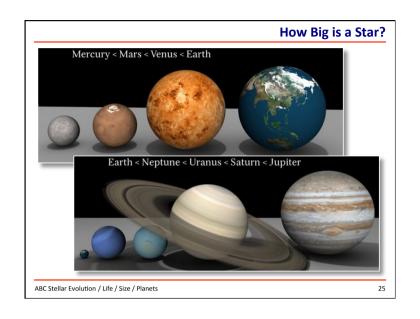

Live Slow, Die Very Old

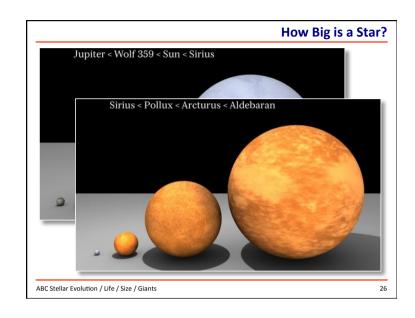

Low Mass stars do not have a lot of fuel, but...

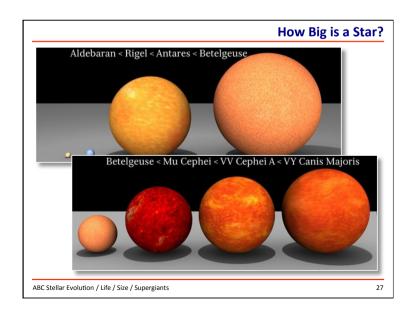

- Gravitational forces are relatively weak
- Hence radiation forces do not have to be high to maintain a balance
- Hence nuclear fuel lasts a long time

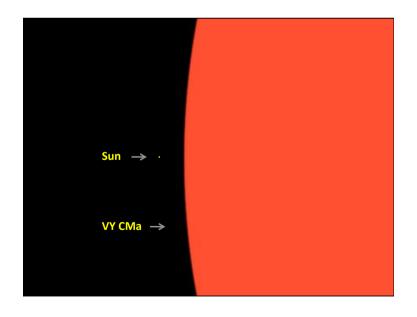

For stars of mass = 10% of the mass of our Sun, we are not even sure what happens when the fuel runs out — it hasn't happened yet in the history of the Universe!

ABC Stellar Evolution / Life / Mass

What Happens When the Fuel Runs Out?

Remember than nuclear fusion (or "burning") does not use up much of the star's mass.

600 million tons of H 596 million tons of He every second

The 4 million tons that is "lost" is converted to energy that is radiated out from the core.

Even after billions of years, 99% of the mass is still there, transmuted from hydrogen into helium.

What happens when the hydrogen runs out?

ABC Stellar Evolution / Life / Heavy Elements

What Happens When the Fuel Runs Out?

Remember the ABC of stellar evolution?

• When the hydrogen runs out, radiation drops

- The star is out of BALANCE as gravity > radiation
- The star shrinks and **COMPRESSION** heats the core to a higher temperature

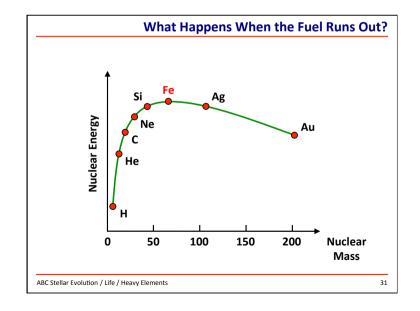

- This forces nuclei together and ACCELERATES the fusion of helium into heavier elements

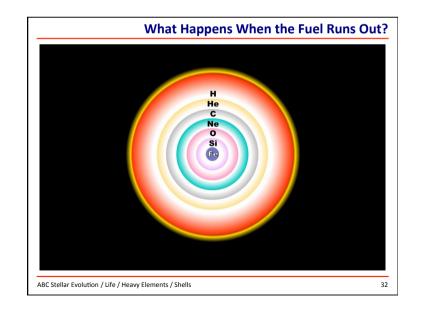

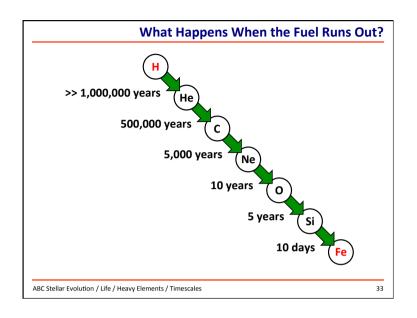

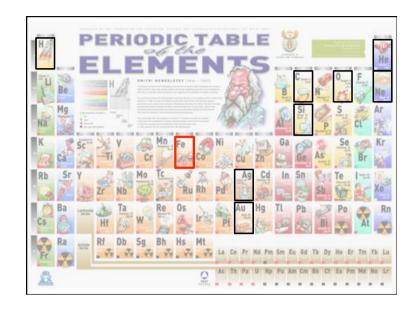

Radiation increases and BALANCE is restored

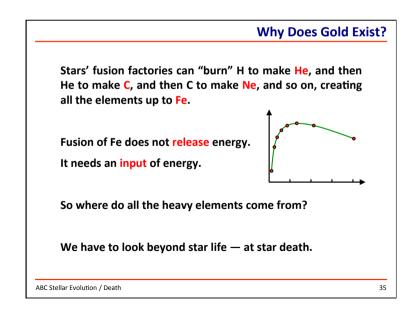

ABC Stellar Evolution / Life / Heavy Elements

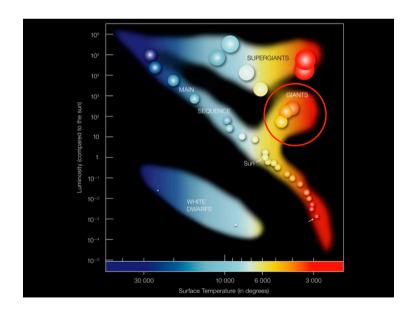

Red Giant or White Dwarf

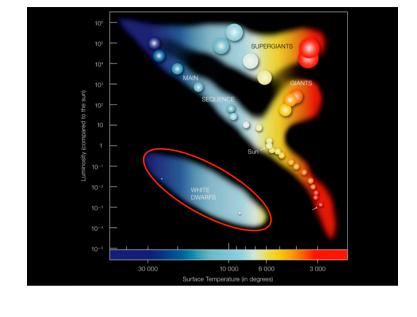

For Medium Mass stars, gravity may not be strong enough to hold on to the outer layers of the star when He starts to burn in the core.

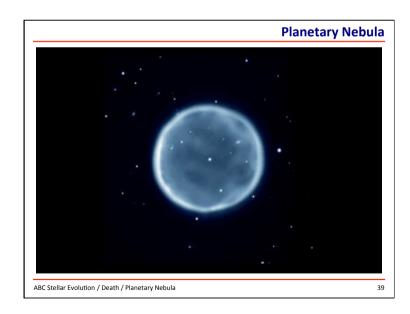

As the star expands the outer layers cool and redden — the star becomes a Red Giant.

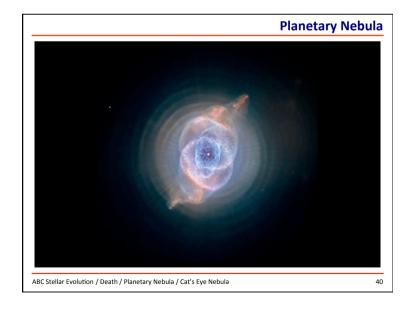

The He burning in the core can become unstable. If the outer layers are given enough energy they can be blown off the star completely, leading to the formation of a Planetary Nebula.

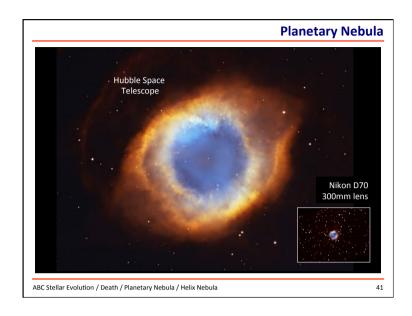

The remaining core becomes a White Dwarf.

ABC Stellar Evolutionth / Red Giant or White Dwarf

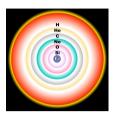

For High Mass stars the strong gravity holds the star together through all the stages of nuclear burning.

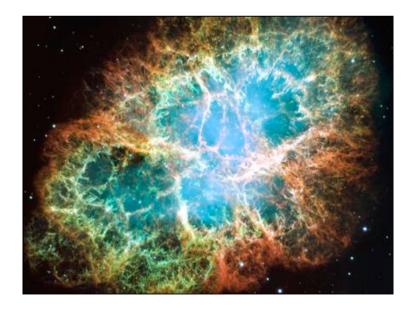

At the end of its life, when the Fe core can no longer provide the energy to support the star, the core undergoes a catastrophic collapse.

The collapse crushes the core to a size of a few kilometres. A shockwave rebounds from the core and ejects the rest of the star's material into interstellar space.

ABC Stellar Evolution / Death / Supernova

42

Supernova

The energy of a supernova explosion is incredible. A back-of-the-envelope calculation shows that to rip a star apart you need an energy of

10⁴⁴ Joules

Imagine the total energy output of the Sun (not just the tiny fraction that falls on the Earth) in each and every second of its 10-billion-year lifetime.

Now imagine all that energy released in just a few seconds.

The word "explosion" just isn't big enough.

ABC Stellar Evolution / Death / Supernova

Supernova

In the mêlée of the supernova explosion nuclei fuse together to create elements heavier than Fe.

All the elements generated during the star's life, and its spectacular death, are ejected into interstellar space.

All the heavy metals found on Earth must have been made in a supernova.

This means that the Sun must be "second generation". An unknown star was born, lived and died billions of years ago to seed our region of space with the heavy elements that we see around us today.

ABC Stellar Evolution / Death / Supernova / Heavy Elements

45

Supernova

After a supernova has crushed the star's core and ripped apart all of the star's outer regions, what is left behind?

A tiny star a few kilometres in diameter.

A Neutron Star.

ABC Stellar Evolution / Death / Supernova / Neutron Star

Supernova

Think about it for a minute...

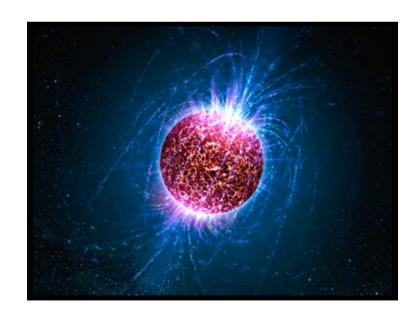

We are just the custodians of 'our' atoms.

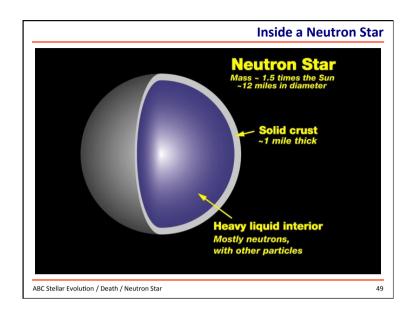

They were made in a star that died in a supernova explosion and redistributed the atoms into space.

We will use them for a while.

In a few billion years our Sun will die and many of those atoms will be recycled back into space for another generation to use.

ABC Stellar Evolution / Death / Supernova / Heavy Elements

When Gravity Wins

Neutron stars formed in supernova explosions have a size of a few kilometres because this is the point at which neutrons are forced to "touch" each other.

Getting them any closer means that they would have to overlap each other, which they really do not want to do.

If the star has enough mass, then gravity wins and the neutrons are forced together despite their objections. Nothing can stop the collapse continuing.

The result is the stuff of science fiction... a Black Hole.

ABC Stellar Evolution / Death / Black Hole
