Ancient Light The light was emitted by the quasar 1.4 billion years after the Big Bang.

It had already been travelling for nearly 8 billion years when the Sun and the Earth were born. It continued on its journey through the void for another 4.5 billion years.

Life evolved on Earth. The light travelled on.

Dinosaurs came and went. The light travelled on.

In the last million years of its journey it arrived at the edge of our Milky Way galaxy, crossed a few spiral arms, and entered the Solar System.

In its last few hours it finally arrived at Earth, travelled through the atmosphere in a fraction of a second, hurtled towards England, dodged a few clouds, and entered the lens and hit the camera sensor.

Just a pixel in the image ... but what a journey!
