## Just a Second

|  | Just a Second |
| :--- | ---: |
| Time and motion |  |
| What is a second? | Motion defines time |
| What can happen in one second? | How is it defined? |
| Earth's rotation is slowing down  <br> What are the consequences? Are seconds getting longer? <br> What is a leap second? Why are they needed? <br> UNivensity of  |  |

How do humans think about time?
Ultimately, we always measure time by the motion of ... something.

| For millennia the passage of |
| :--- |
| time has been measured by the |
| motion of astronomical objects |
| such as the Sun moving across |
| the sky during the day ... |
| ... or the changing phases of the |
| Moon at night. |

UNIVERSITY OF

|  |  | What Is a Second? |
| :---: | :---: | :---: |
| Surely that's trivial - the Earth spins on its axis once a day, where |  |  |
| 1 day $=24$ hours | 1 hour $=60$ minutes | 1 minute $=60$ seconds |
| So one second | $\frac{1}{24 \times 60 \times 60}$ |  |
|  | $\frac{1}{86400}$ | of one day. |
| Simples! |  |  |
| So that's the end of the talk ...? No. Let's look at how the Earth moves. |  |  |

## Just a Second

## What Is a Second?

Since 1968 the second has had the precise definition of

$$
9,192,631,770
$$

oscillations of a caesium atom (or, more accurately, the microwave radiation corresponding to the transition between two energy levels of the isotope caesium-133).

This is called the caesium standard.

## Just a Second

So What?

So a day is not an exact number of seconds. So what?
It's just like the problem we have with a year not being an exact number of days.

$$
1 \text { year = } 365.2422 \text { days }
$$

If not addressed, the calendar would drift very slowly relative to the seasons. Inserting an extra day every fourth year would make the calendar year $=365.25$ days. Almost right.

Skipping a leap day in a century year that is not divisible by 400 makes the calendar year $=365.2425$ days. That's pretty close.
univestivo of

So What?
If we want our 24-hour clocks to stay synchronised with the rotation of the Earth (so that the Sun is in the sky when our clocks say it is daytime) then we need to add leap seconds every once in a while.
( Actually, we don't NEED to. Alternatively, we could keep clocks synchronised with the rotation of the Earth by letting seconds get longer as the Earth slows down.

However, scientists would be furious!
Atomic clocks would have to be set to run at slower and slower rates. Having the definition of the second change every few minutes would be totally impracticable.)

## Just a Second

Leap Seconds

When should leap seconds be inserted into a day? Local midnight? But midnight where? Every time zone has its own midnight.

If leap seconds are not inserted at the same instant, clocks around the world will be out of synch by up to 1 second. In the world of global electronic finance, that lack of synchronisation matters.

## Leap Second Smearing

Some people really don't like leap seconds.
Some computer systems really don't like leap seconds.
Some companies really don't like leap seconds.
For instance, Google use leap second smearing to avoid the minute before midnight having 61 seconds. They add the leap second, a few microseconds at a time, continuously throughout the day.

They do this by running their clocks $0.001 \%$ slow for a day
Imagine doing that with a leap day ...
