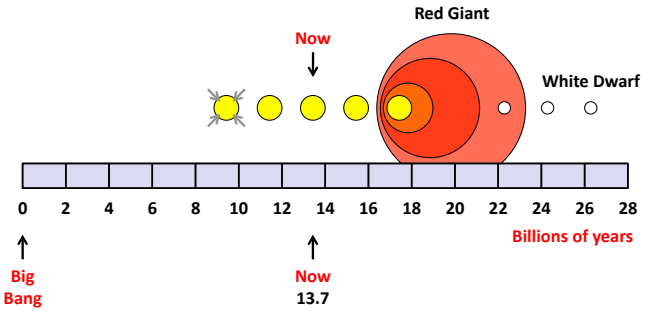
	When Gravity Wins	Black Hole

Life Cycle of the Sun

Our Sun is middle-aged…

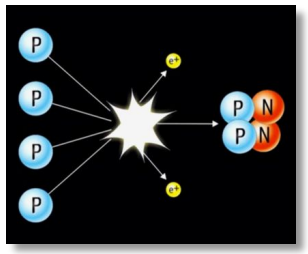


[Sizes not to scale]

At the Heart of the Matter

In the core of a star, where the pressure and temperature conditions are right, the fusion of hydrogen into helium releases energy.

4 x hydrogen



1 x helium

600 M'tons

596 M'tons

Fusion

Stars are not just nature's way of lighting up the universe…

they are the "fusion factories" that make the elements heavier than hydrogen.

BUT…

Where does the hydrogen come from in the first place?

That's a very good question, but the answer is too long to be given here. Perhaps the solution is a future talk on the "The Beginning of Everything"?

How Stars Tick / Fusion 5

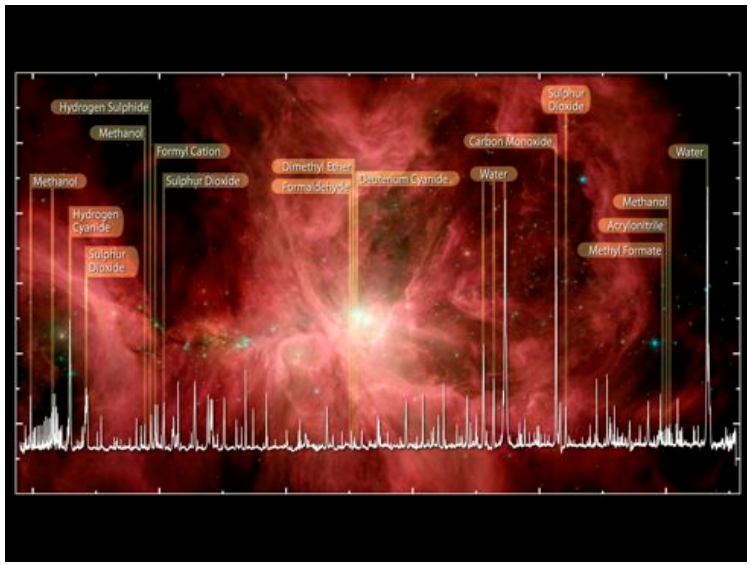
Star Formation

Where do stars come from?

Anyone can make a star in 7 easy-to-follow steps…

1. Start with a big cloud of hydrogen
2. Wait…
3. Wait some more…
4. Wait a bit longer…
5. Wait another 100,000 years…
6. Wait a bit longer…
7. You now have a star

How Stars Tick / Birth 6



What Triggers Star Formation?

Giant Molecular Clouds float around the galaxy

- They look like clouds
- They consist mainly of hydrogen molecules
- They are big (~100 light years across)

What makes a GMC collapse? Triggers may include…

- One cloud colliding with another
- Shock waves rippling through the cloud
- Galaxy collisions (!)

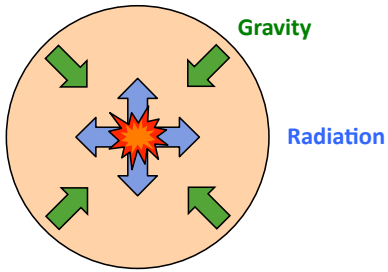
A Question of Balance

All stars are a balance between the opposing forces of gravity and radiation pressure.

When the opposing forces are balanced, the star is stable.

When out of balance, the star must evolve.

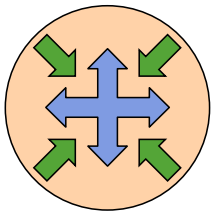


Many aspects of star birth, life and death can be explained in terms of this balance and the ABC of star evolution.

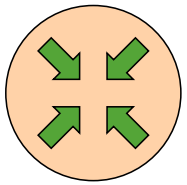
How Stars Tick / Life / Balance 20

The ABC of Star Evolution

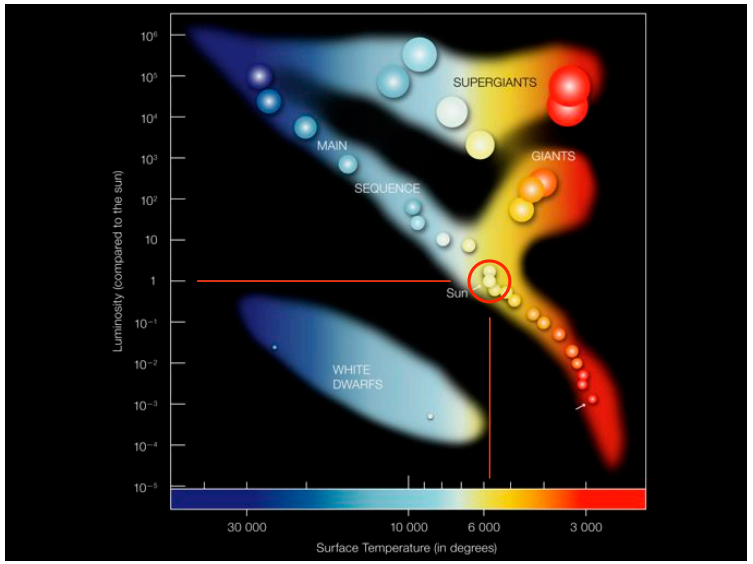
Like charges repel so high T and high P **ACCELERATE** fusion



In a star in equilibrium gravity and radiation are in **BALANCE**

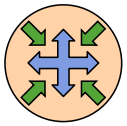


COMPRESSION produces heat



Live Fast, Die Young

Stars of different **mass** follow quite different lives.



High Mass stars have a lot of fuel, but…

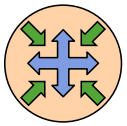
- Gravitational forces are very strong
- Balance requires a lot of radiation to be generated
- Nuclear fuel must be used at a prodigious rate

Rather than living for **billions** of years, like our Sun, high mass stars may live for only a few **million** years.

Live Slow, Die Very Old

Low Mass stars do not have a lot of fuel, but…

- Gravitational forces are relatively weak
- Hence radiation forces do not have to be high to maintain a balance
- Hence nuclear fuel lasts a long time



For stars of mass = 10% of the mass of our Sun, we are not even sure what happens when the fuel runs out — it hasn't happened yet in the history of the Universe!

What Happens When the Fuel Runs Out?

Remember than nuclear fusion (or "burning") does not use up much of the star's mass.

600 million tons of H → 596 million tons of He

every second

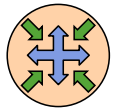
The 4 million tons that is "lost" is converted to energy that is radiated out from the core.

Even after billions of years, 99% of the mass is still there, transmuted from hydrogen into helium.

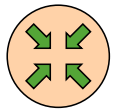
What happens when the hydrogen runs out?

What Happens When the Fuel Runs Out?

Remember the ABC of stellar evolution?



- When the hydrogen runs out, radiation drops
- The star is out of BALANCE as gravity > radiation



- The star shrinks and COMPRESSION heats the core to a higher temperature
- This forces nuclei together and ACCELERATES the fusion of helium into heavier elements

- Radiation increases and BALANCE is restored

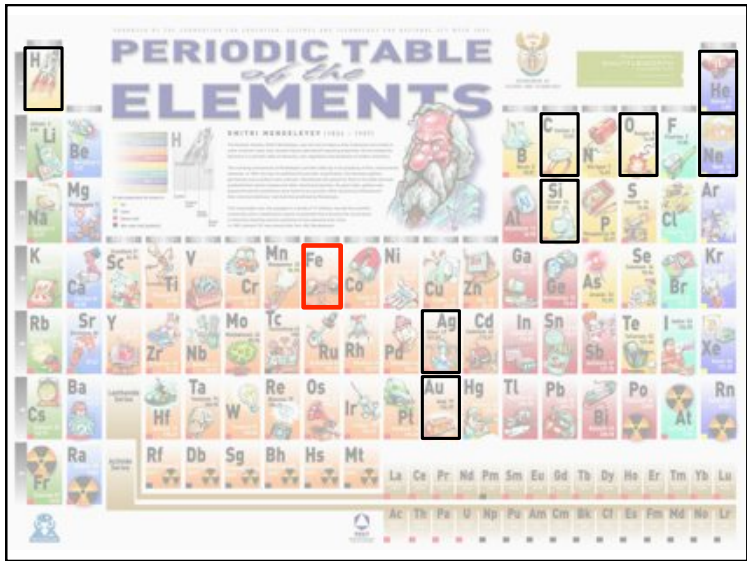
How Stars Tick / Life / Heavy Elements / Timescales 33

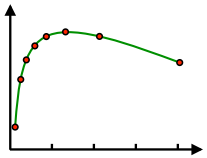


Why Does Gold Exist?

Stars' fusion factories can "burn" H to make He, and then He to make C, and then C to make Ne, and so on, creating all the elements up to Fe.

Fusion of Fe does not release energy.

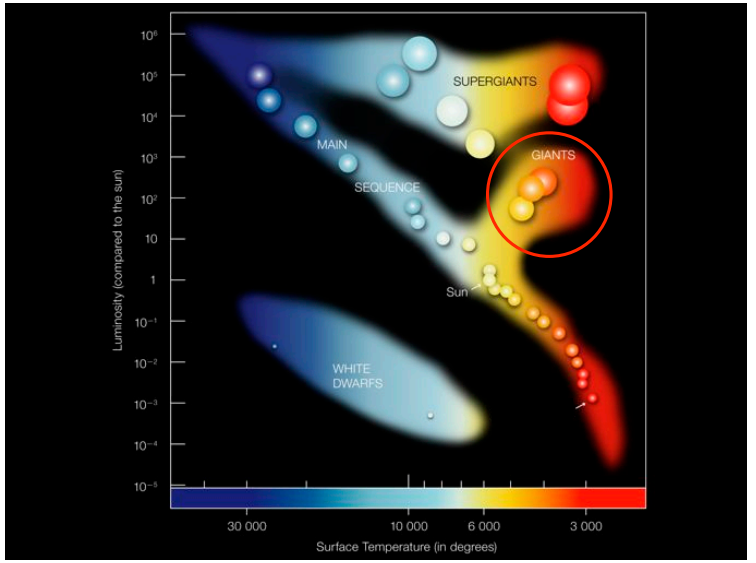
It needs an input of energy.



So where do all the heavy elements come from?

We have to look beyond star life — at star death.

How Stars Tick / Death 35



Red Giant or White Dwarf

For **Medium Mass** stars, gravity may not be strong enough to hold on to the outer layers of the star when He starts to burn in the core.

As the star expands the outer layers cool and redden — the star becomes a **Red Giant**.

The He burning in the core can become unstable. If the outer layers are given enough energy they can be blown off the star completely, leading to the formation of a **Planetary Nebula**.

The remaining core becomes a **White Dwarf**.

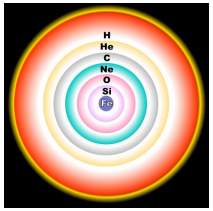
Supernova

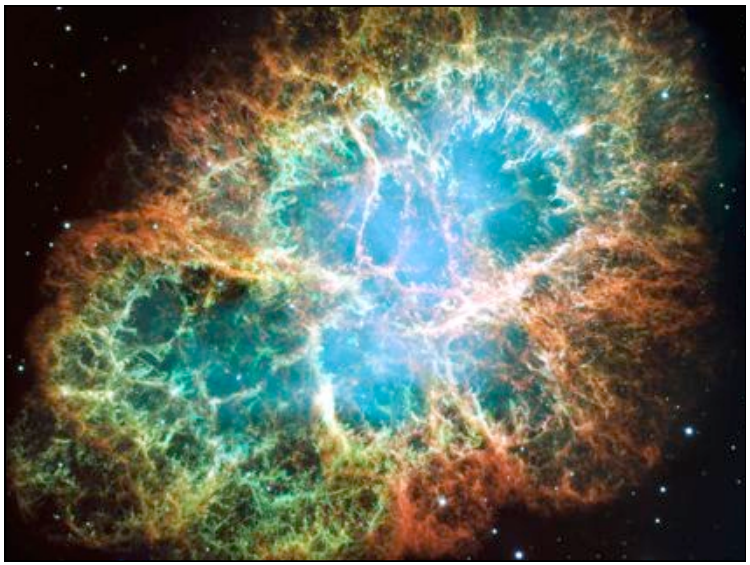
For High Mass stars the strong gravity holds the star together through all the stages of nuclear burning.



At the end of its life, when the Fe core can no longer provide the energy to support the star, the core undergoes a catastrophic collapse.

The collapse crushes the core to a size of a few kilometres. A shockwave rebounds from the core and ejects the rest of the star's material into interstellar space.

How Stars Tick / Death / Supernova 42



Supernova

The energy of a supernova explosion is incredible. A back-of-the-envelope calculation shows that to rip a star apart you need an energy of

$$10^{44}$$ **Joules**

Imagine the total energy output of the Sun (not just the tiny fraction that falls on the Earth) in each and every second of its 10-billion-year lifetime.

Now imagine all that energy released in just a few seconds.

The word "explosion" just isn't big enough.

How Stars Tick / Death / Supernova 44

Supernova

In the mêlée of the supernova explosion nuclei fuse together to create elements heavier than Fe.

All the elements generated during the star's life, and its spectacular death, are ejected into interstellar space.

All the heavy metals found on Earth must have been made in a supernova.

This means that the Sun must be "second generation". An unkown star was born, lived and died billions of years ago to seed our region of space with the heavy elements that we see around us today.

Supernova

Think about it for a minute…

We are just the custodians of 'our' atoms.

They were made in a star that died in a supernova explosion and redistributed the atoms into space.

We will use them for a while.

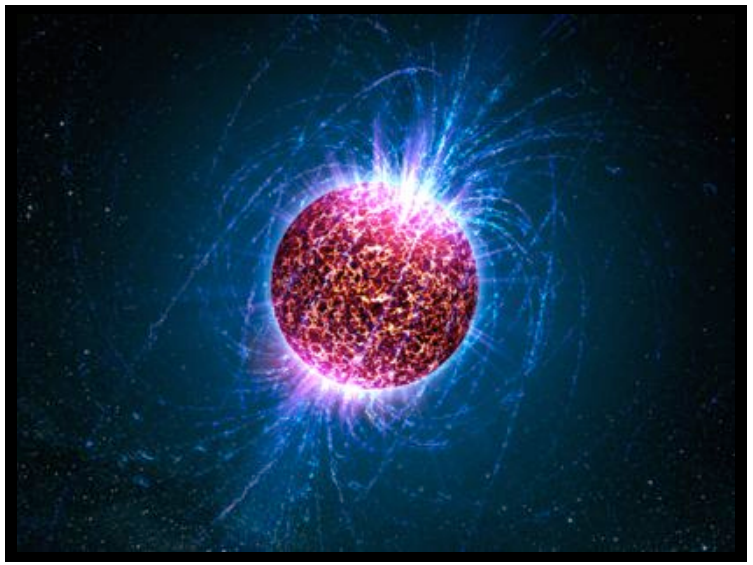
In a few billion years our Sun will die and many of those atoms will be recycled back into space for another generation to use.

Supernova

After a supernova has crushed the star's core and ripped apart all of the star's outer regions, what is left behind?

A tiny star a few kilometres in diameter.

A Neutron Star.



Inside a Neutron Star

Ticking Pulsars

Pulsar name	Period
B0329	814 ms
Vela Pulsar	89 ms
Crab Pulsar	33 ms
J0437	5.7 ms
B1937	1.5 ms
	1.55780644887275 ms

How Stars Tick / Death / Neutron Star / Pulsars 50

When Gravity Wins

Neutron stars formed in supernova explosions have a size of a few kilometres because this is the point at which neutrons are forced to "touch" each other.

Getting them any closer means that they would have to overlap each other, which they really do not want to do.

If the star has enough mass, then gravity wins and the neutrons are forced together despite their objections. Nothing can stop the collapse continuing.

The result is the stuff of science fiction… a Black Hole.
