

A Brief History

Black Hole [definition]:

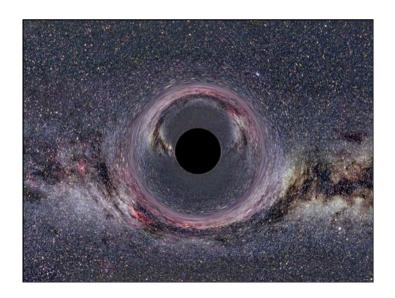

A region of space from which nothing, not even light, can escape.

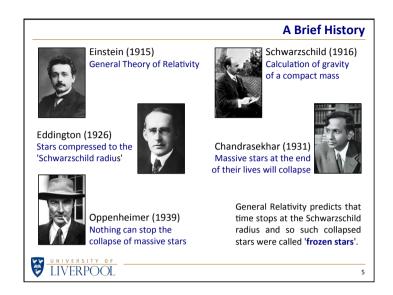

When did the concept of a black hole originate? Earlier than you think.

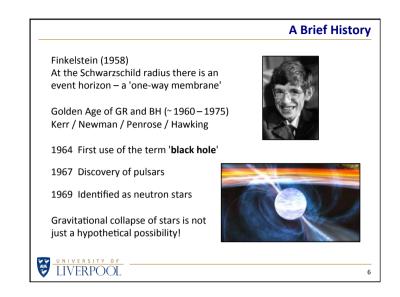

Rev John Michell (1783) – "If [the size of] a sphere of the same density of the Sun were to exceed that of the Sun in the proportion of 500 to 1 \dots all light emitted from such a body would be made to return towards it by its gravity."

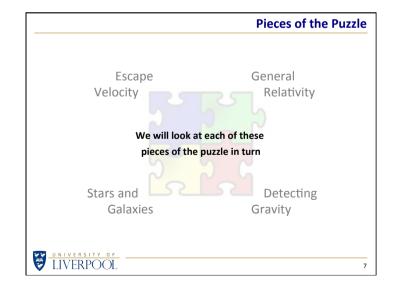

In the 1800s the idea of such 'dark stars' was largely ignored.

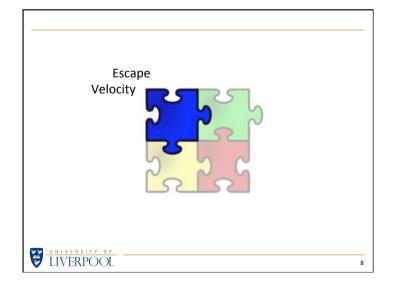

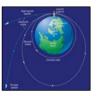

Escape Velocity

What goes up must come down? Right?

Wrong, not if it goes up fast enough.

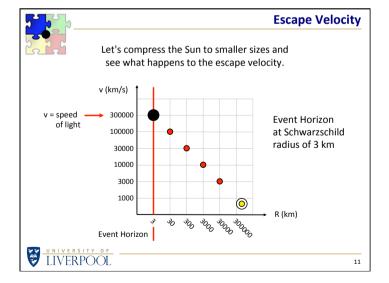

The threshold speed needed for an object to escape the gravitational pull of a body is called the escape velocity. If you throw something up with a speed less than the escape velocity then it will fall back.

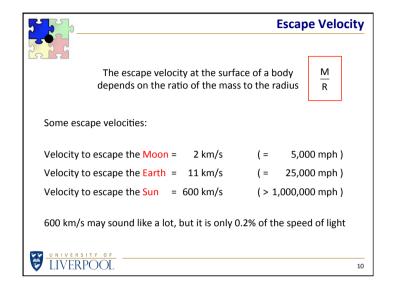

The force of gravity pulling an object (like you) towards a body (like the Earth) depends on both of the masses involved and the distance between them. The escape velocity does not depend on the mass of the object — the escape velocity for a 1 kg satellite is the same as for a 1 ton satellite or even a 1000 ton space station.

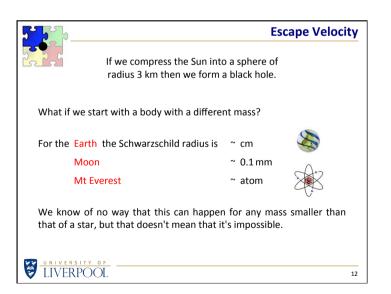

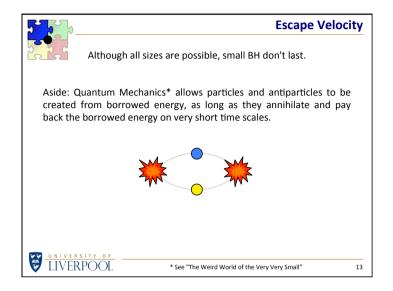

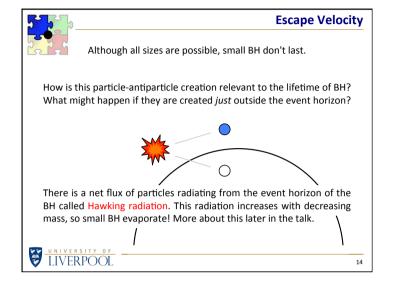

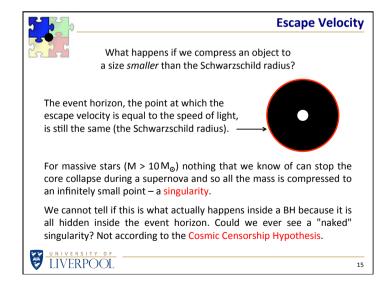

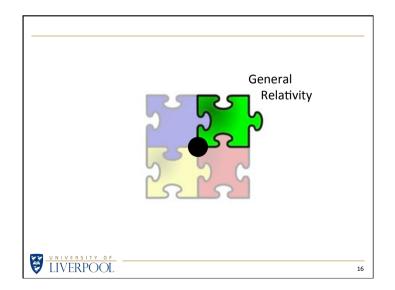

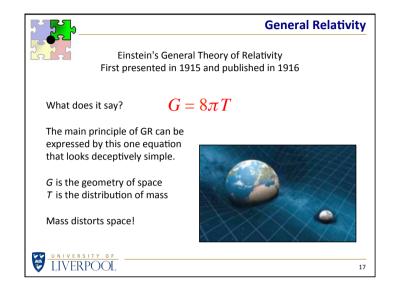

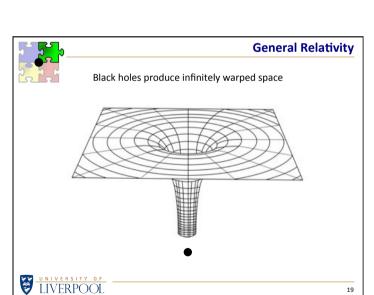

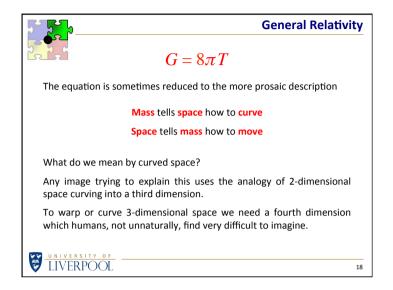

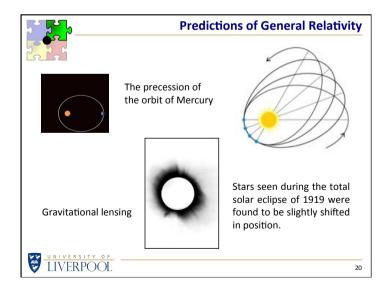

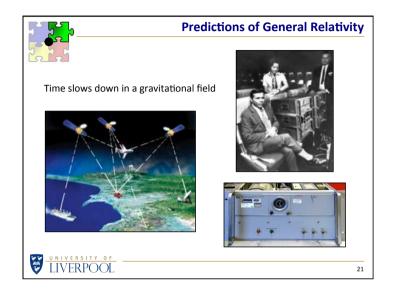

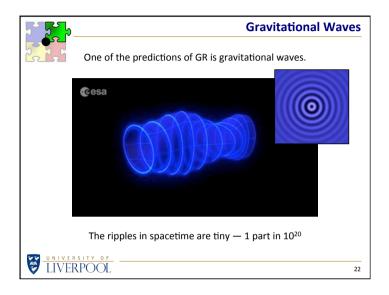

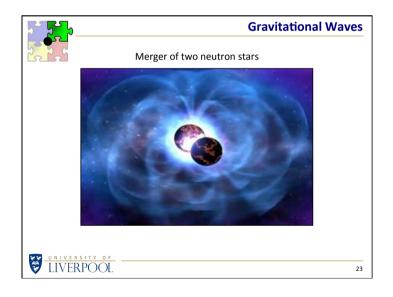

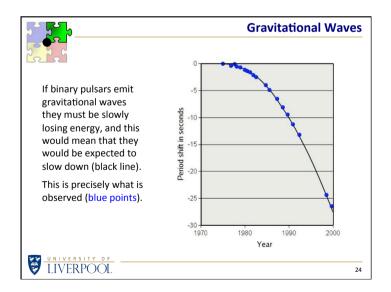

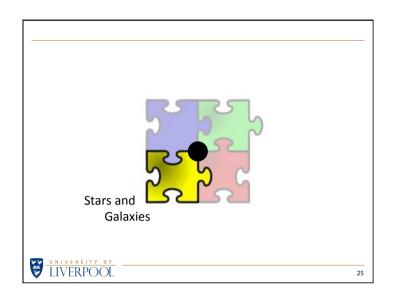

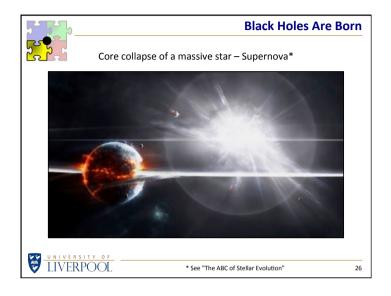

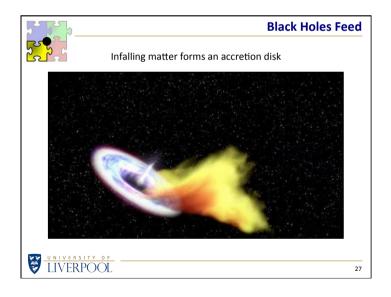

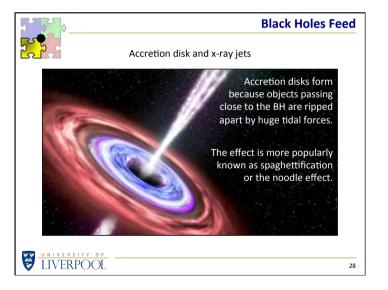

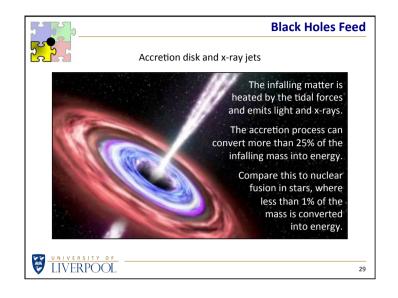

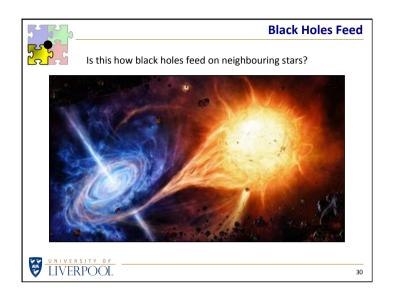

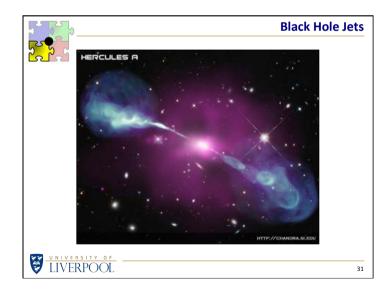

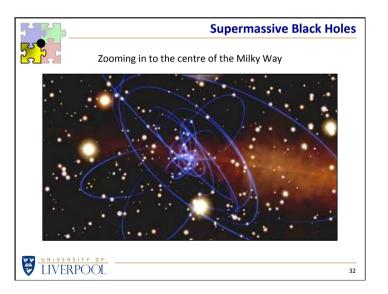

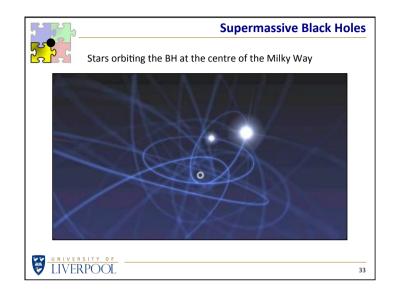

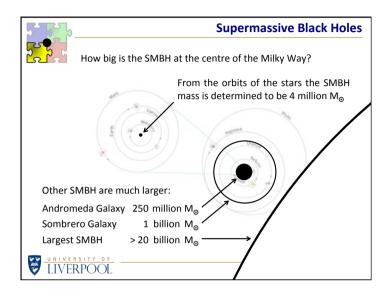

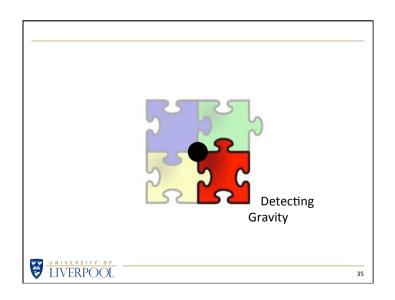

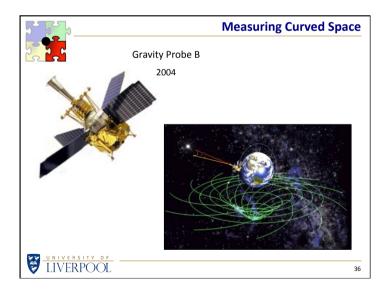

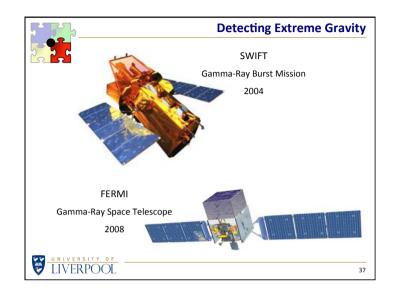

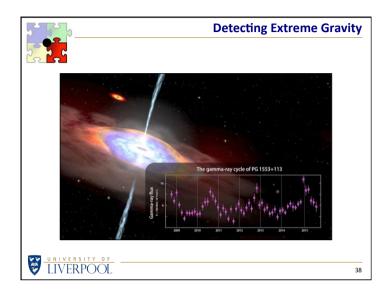

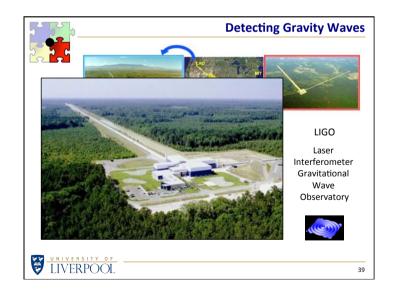

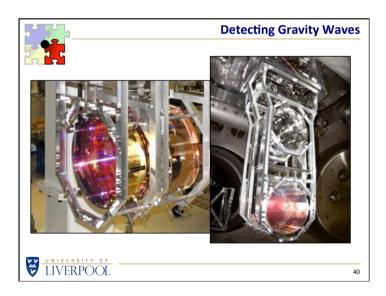

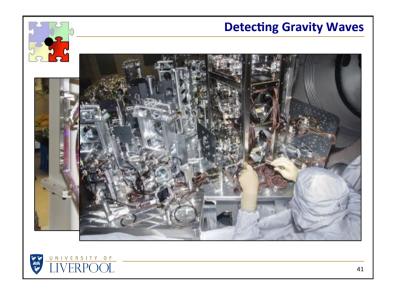

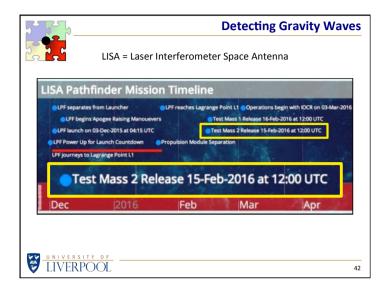

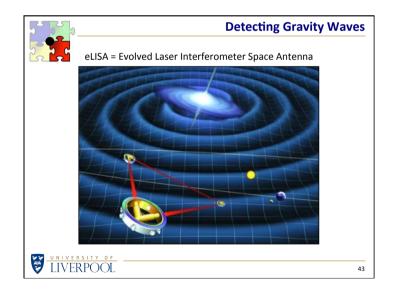

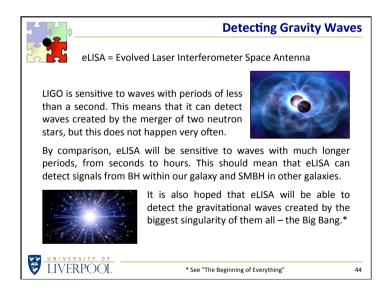

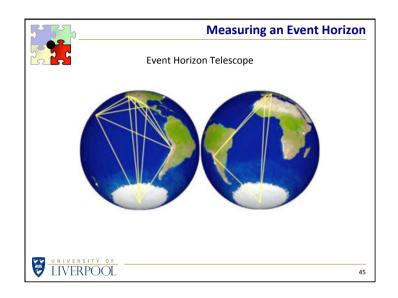

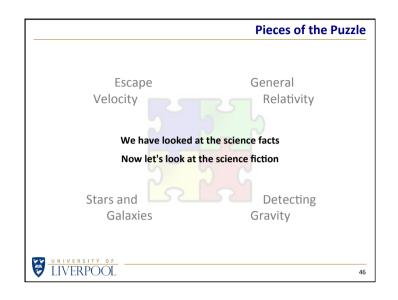

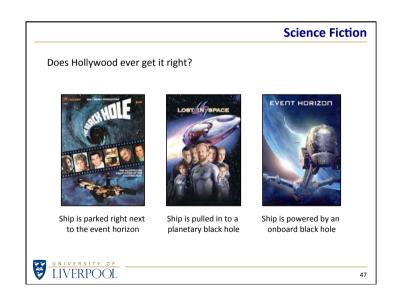

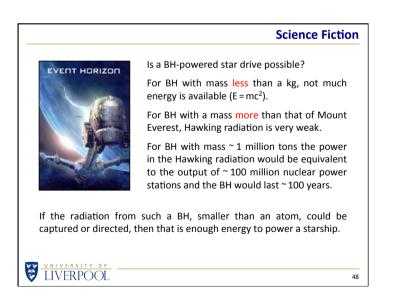

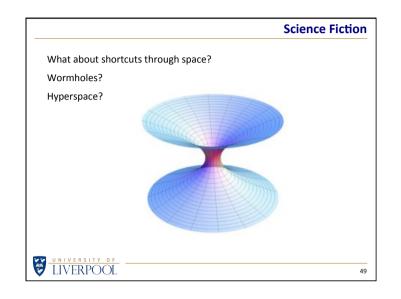

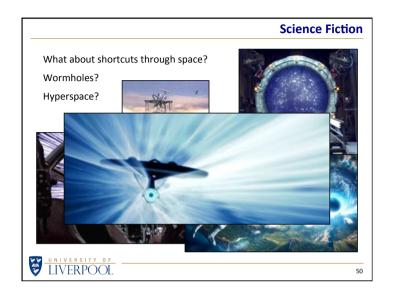

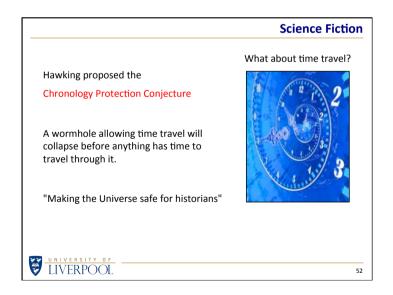

The Problem

There's a problem.

General Relativity (GR) works really well for massive objects (like stars).

Quantum Mechanics (QM) works really well for tiny objects (like atoms).*

But, what if the object is massive **and** tiny?

Then we need (drum roll) ... Quantum Gravity.

The problem: GR and QM are not good bedfellows.

A universal 'Theory of Everything' has proven to be elusive.

The Future

Maybe quantum mechanics will prevent a singularity from forming, thus avoiding the horrible properties like infinite density and infinitely warped space.

For instance, String Theory describes a ten-dimensional universe in which the fundamental building blocks are 'strings' rather than the more familiar 'particles'.

If String Theory is right, black holes are 'fuzzballs' without a singularity at their core. They are just 'balls of string'.

But, is the universe described by String Theory the one in which we live?

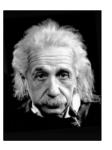

--

The Future

Einstein never really believed that quantum mechanics was the right description of the microscopic world.

He spent most of his later years wrestling with a Theory of Everything.

If a genius like Einstein could not get his head around the problem, what will it take?

Maybe some unexpected discoveries, for instance from LIGO or eLISA, will point the way forward to a better understanding of black holes.
